

THE
British Medical Journal.

THE JOURNAL OF THE BRITISH MEDICAL ASSOCIATION.

EDITED BY

SIR DAWSON WILLIAMS, M.D., D.Sc., D.LITT.

AND

NORMAN GERALD HORNER, M.A., M.B.

VOLUME I, 1921.

JANUARY TO JUNE.

London :

PRINTED AND PUBLISHED AT THE OFFICE OF THE BRITISH MEDICAL ASSOCIATION,
429, STRAND, W.C.

LIST OF ILLUSTRATIONS.

SPECIAL PLATES.

	PAGE		PAGE
Astragalus, Rotation-Dislocation of (Robert Ollerenshaw) facing	155	Gunshot Injury to the Brain (Judson S. Bury) ...	557
Coccygeal Fistulae (J. P. Lockhart-Mummery) ...	facing 806	Heart-block (T. Wardrop Griffith) ...	763
Encephalitis Lethargica, Histo-pathology of (C. Da Fano) facing	154	Heart, Dilatation of (D. W. Samways) ...	189
"Harlequin Foetus" (J. T. McAuslin) ...	facing 155	Intestinal Obstruction after Ventrofixation, Prevention of (Alexander Don) ...	563
Hour-glass Stomach (C. Thurstan Holland) ...	facing 6, 7	Knee-cap, Improved ...	164
Idiopathic Muscular Dystrophy (R. S. Carter and W. Fleming) ...	facing 807	Manometer for Intrapericardial Pressure, a Portable ...	465
Infective Arthritis and Allied Conditions (W. H. Willcox) facing	806	Massage of Heart and Resuscitation (J. A. Gunn) ...	11
Osteomyelitis, Acute, of the Long Bones in Children (Alex. Mitchell) ...	facing 807	Metal limbs, Light, in Above-knee Amputations (Edred M. Corner) ...	524
		Microsporcn, Unusually Virulent Variety of (Robert Craik) ...	672
		Mouth Gag, an Improved ...	127
		Muscle-Tonus, Tonic Rigidity and Tonic Fits (Sir James Purves Stewart) ...	217
		Needles, Surgical ...	127
		Newcastle-upon-Tyne and District, Views of ...	391, 577, 830
		Pelvic Drain, Device to Assist in the Introduction of ...	197
		Physiological Cost of Muscular Work Measured by Exhalation of Carbon Dioxide (A. D. Waller and G. De Decker) ...	669
		Pre-masseteric Fistulae of Stenson's Duct, Operation for the Radical Cure of (Gilbert Chubb) ...	46
		Retinoscope, a Double ...	307
		Reverdin Needle and Holder, Standardized ...	465
		Rhizotomy for the Relief of Pain (Sir William Thorburn) ...	629
		Scotometer, Direct Record ...	645
		Stenosis at the Internal Meatus after Suprapubic Prostatectomy (Andrew Fullerton) ...	301
		Temperature Relation to Cardiac Irregularity (R. Macnair Wilson) ...	226
		Tuberculin Administration, Tray for ...	273
		Tuberculosis Mortality, 1919 ...	202
		Tuberculosis, Pulmonary, Statistics on the Prevention of (Surgeon Commander D. H. C. Given) ...	645
		Urethral Drainage Bougie ...	187
		Vater peduncularis in Malarial and Blackwater Fevers (Lieut.-Colonel J. C. S. Vaughan) ...	187

ILLUSTRATIONS IN THE TEXT.

Anaesthetist's Screen ...	743
Aneurysmorrhaphy, Reconstructive (C. Jennings Marshall) ...	379
Appendix Clamp ...	568
Asthma and Anaphylaxis (Frank Coke) ...	372
Auricular Flutter and Fibrillation (Thomas Lewis) ...	551, 591
Catheter Holder for Intrauterine Treatment of Gonorrhoea ...	569
Cleft Palate: New Principle in the Treatment of (H. D. Gillies and W. Kelsey Fry) ...	336
Disturbed Reflexes in the Production of Symptoms (Sir James Mackenzie) ...	147
Draining Rack ...	781
Duval's Lung Forceps, Modification of ...	273
Eclipse Blindness (William Oliver Lodge) ...	701
Ether Inhaler, Compact Warm ...	935
Exomphalos, or Hernia into the Umbilical Cord (Robert Tenison) ...	264
Fractures, Treatment of (S. Alwyn Smith) ...	483
Gas-oxygen ether Outfit, Improvements for Use with ...	19
Gastroptosis, Diagnosis and Treatment of (Major John F. Hall-Edwards) ...	698
Genito-urinary Surgery, Two Instruments for ...	568
Giant, Notes on (William Robinson) ...	560

INDEX TO VOLUME I FOR 1921.

READERS in search of a particular subject will find it useful to bear in mind that the references are in several cases distributed under two or more separate but nearly synonymous headings—such, for instance, as Brain and Cerebral; Heart and Cardiac; Liver and Hepatic; Renal and Kidney; Cancer and Carcinoma, Epithelioma, Malignant Disease, New Growth, Sarcoma, etc.; Child and Infant; Bronchocele, Goitre, and Thyroid; Diabetes, Glycosuria and Sugar; Light, Roentgen, Radium, X Rays; Status Lymphaticus and Thymus; Eye, Ophthalmia and Vision; Bicycle and Cycle; Motor and Automobile; Association, Institution, and Society, etc. Subjects dealt with under various main headings in the JOURNAL have been set out in alphabetical order under their respective headings—for example, "Correspondence," "Leading Articles," "The Week," "Reviews," etc. Original Articles are indicated by the letter (O).

A.

ABBOTT, William Frederick, obituary notice of, 447

Abdominal affections, acute, early diagnosis of (W. McAdam Eccles), 663 (O)—Correspondence on, 759

Abdominal pain, its mechanism and clinical significance (A. E. Majlard), 731 (O)

Abdominal pain in childhood, diagnostic significance of (Robert Hutchison), 1 (O)

Abdominal tuberculosis. See Tuberculosis

Abdominal tumour. See Tumour

ABRAHAM, H. M. Albuminuria and life assurance

Abortion, instrumental (Bernard H. Spillbury), 461

ABRAHAM, Phineas Simon obituary notice of, 406

Académie de Médecine. Centenary, 26—M. Richelot becomes President, 165—Most suitable time for calling men to the colours, 157

ACADEMY, ROYAL OF MEDICINE, IN IRELAND

Section of Medicine—Case of bubonic plague in Dublin, 81

Section of Obstetrics—"Vicious menstruation," discussion on, 85—Fibrous and muscular attachments of the vagina, 778—Primary carcinoma of the vagina, 778

Section of State Medicine—Medical reform in Ireland, 344

Section of Surgery—Modern surgery of the elbow, 48

Accessory food factors. See Food and Vitamin

ACARDI, Professor elected General Secretary of the Académie de Médecine, 878

Achondroplasia, hydrocephalus in, 435

Acid dentifrice, 408, 550

Acid diacetic, tests for, 841

Acid fumes poisoning from. See Poisoning

Acidaemia (Sir Almoth Wright), 319

Acidosis and alkalosis, 508, 542

ADAM, James Asthma and anaphylaxis, 478

ADAM, J. G. Pathology of influenza, 48

ADAMS, John Congenital syphilis, 460

ADAMS, J. E. Exophthalmic goitre, 342—Surgery of the right iliac fossa, 674

Adams-Stokes syndrome and heart-block, 755

ADAMSON, H. G. Relation of skin disease to internal disorder, 303

ADAMSON, R. O. Treatment of gastric and duodenal ulcers, 122—Early diagnosis of acute abdominal affections, 759

ADDISON, Right Hon. Christopher. Dinner to, 532—Leading article on 535—Parliamentary note on 575—Appreciation of by National Association of Insurance Committees, 661—Cavendish lecture on the part of the State in the prevention of disease, 940

ADDISON, O. L. Congenital syphilis, 343

Adenitis tuberculous (E. C. Lewis), 780

Adenoid and tonsil operations in outdoor clinics, risks after, 32 65 101 140, 174, 213, 245 285, 321 365, 404, 443—Leading article on, 167

Adenoids, medical treatment of. See above

Adjustments, fine (leading article), 432

Admiralty surgeons fees. See Fees and Navy, Royal

Adrenaline in resuscitation from apparent death (Cranston Walker), 46 (O) 100—A disclaimer 100—Correspondence on, 102 136, 482, 544, 582. See also Resuscitation

"Aesthesiopsia abdominalis," 435

Africa, South, and the British Medical Association, 363. See also Association

Africa, South reciprocity with, 949—Medical Congress, 599

After Care Association. See Association

AGAR, Wilfred, elected Fellow of Royal Society, 357

Age and pensions, 249, 370

Air Force Nursing Service, the Royal, regulations, 625

Air ambulances, 434

ATCHISON, R. S. A Medical Handbook for the Use of Practitioners and Students, rev. 164

ALDER, Fred H. Orthopaedic and Reconstruction Surgery. Industrial and Civilian, rev. 85

ALDER, Professor, death of, 878

Albuminuria, intermittent, in children (F. Moor), 671 (O)

Albuminuria in relation to life assurance (F. Parkes Weber), 78 (O), 83—Discussion on, 83

Alcohol in medicine, use of (H. H. Dale), 603—Discussion, 609

Alcoholism, treatment of, 750—Report of Dalrymple House, 750

Aloppo, small Italian surgical hospital opened at, 562

Alimentary disorders, faeces in (Robert Cooper), 528

Alkaline dentifrice, 692, 725

Alkaloids and glucosides, 59

Alkalosis and acidosis. See Acidosis

ALLAN, James W. Evolution in relation to disease, 722

ALLDUTT, Sir Clifford. Comparative medicine, 356—Eradication of tuberculosis, 422—Heart-block and the Adams-Stokes syndrome, 755—Pronunciation of vitamin, 828

ALLEN, F. J. The beginnings of life, 64

ALLER, E. J. Complete heart-block in case of diphtheria, 26 (O)

Allen and Hanbury's *Medicamenta Recentia*, 448

ALLISON, T. M. Asthma and anaphylaxis, 511

Amazilia (amastila), 369

Ambulance plans, emergency, 616

Ambulances, home service, 237—Report, 237, 795—Air, 434

Anenorrhoea following severe trauma (James Hendry), 779

America. See United States

American Field Marshal (W. W. Keen), 279

American Journal of Hygiene, 107

American Journal of Obstetrics and Diseases of Children ceases publication, 215

American Journal of Obstetrics and Gynaecology first number, 215

American Medical Association. See Association

American University (leading article), 864

Amoebic dysentery. See Dysentery

Amputations, above-knee light metal limbs in (Edred M. Corner), 524 (O)

Anaemia, pernicious repeated doses of calomel recovery (John C. Ferrier), 932

Anaemia, pernicious, splenectomy in (leading article), 470

Anaemia splenic. Banti's disease (Sir Berkeley Moynihan), 114 (O)

Anaesthesia, ethanasesal. See Ethanasesal

Anaesthesia and post-operative morbidity (Torrance Thomson), 194

Anaesthesia, resuscitation in death under. See also Heart massage and Resuscitation

Anaesthesia, review of books on, 164, 741

Anaesthetic, a new ethanasesal" (R. L. MacKenzie Wallis and C. Langton Hower), 565

Anaesthesiologist in plastic surgery (Mr. Rowbotham and Mr. Macgill), 344

Anaesthesiologists screen, 743

Anaesthesia, examination before (R. W. Apperley), 528

Anaphylaxis and asthma (Frank Coke), 372 (O)—Correspondence on, 443, 478, 511, 531

Anaphylaxis and immunity (H. H. Dale), 820

Anatomical studies (parliamentary note), 654

Anatomy human, the teaching and study of (Richard J. A. Berry), 75 (O)—Correspondence on, 143

Anatomy, review of books on, 17, 272, 387

ANDERSON, G. C. The private clinic, 939

ANDERSON, H. K. elected a member of the Athenaeum Club, 761

ANDERSON, W. Campbell. Epilepsy considered as a symptom, 444

Aneurysm of external carotid artery treated by ligation of common carotid artery and internal jugular vein (W. A. Peverley and J. K. Haworth), 339 (O)

Aneurysms treated by wiring (Sir D'Arcy Power), 427

Aneurysmorrhaphy, reconstructive, in the thigh, part of the axillary artery (C. Jennings Marshall), 379 (O)

Angina pectoris, with auricular fibrillation (Hamilton M. Sandison, with a note by Frederick W. Price), 339 (O)

Angina pectoris, review of book on, 125

Angina pectoris, surgical treatment of (leading article), 825

Angio-neurotic oedema, 180 490, 545

Angio-neurotic oedema treated by horse serum, 63, 102

Aniline factory workers, tumour of bladder among, 645. See also Tumour

Animal diseases communicable to man (Professor Hobday), 351. See also Mange

Ankylostomiasis campaign in Egypt (A. F. MacCallan), 674

ANVRS E. G. called to the Bar, 918

ANSPACIT Brooke M. Gynaecology, rev. 893

Anthracite, stove for cooking and heating Anthrac, 959

Anthony, cutaneous, treatment of (W. H. O'Neill and A. W. Hall), 883 (O)

Anthrax from shaving brushes, 207, 573, 839

Antistreptococcal serum, the use of (Frances Treas), 77 (O)

Antimalaria. See Malaria

Antimony tartrate in bilharziasis (F. O. Lasbrey and B. B. Coleman), 299 (O)

Antimony in leprosy (F. G. Cawston), 419

Antimony treatment for ex service men suffering from bilharziasis (parliamentary note), 476

Antimony for venereal granuloma (W. E. Giblin), 932

Antimony. See also Tartar emetic

Antisepsis and aseptis, review of book on, 386

Antitetanic serum, large doses of, successful in a case of severe tetanus, 121

Antlers, review of book on, 195—Correspondence on, 247

Antlers, start, and evolution, 247

Aortic blood pressure. See Blood

Aortic incompetence, blood pressure readings in (O. K. Williamson), 734 (O)

Aphasia, a new study of (leading article), 863, 916—Correspondence on, 913

Aphasia, sensory, review of book on 706

Apothecaries Society of London. Pass lists and decrees, 106, 407, 840

Apothecary poet (heats), 360 995

Appeal tribunals. See Pensions

Appendicitis, dental caries and gastric ulcer, 920

Appendicitis simulated by mesenteric lymphadenitis (J. W. Struthers), 706

Appendix clamp, 568

Appendix communicating with colon, 146

Appendix, "double," 762

APPERLEY, R. W. Examination before anaesthesia, 523

Approved societies and hospitals (parliamentary note), 576

ARCHER HALL, H. W. Eclipse blindness, 837

Archivos de Medicina Cirugia y Especialidades, 347

Argentine. Tuberculosis mortality in Rio de Janeiro, 739

ARMOUR, Donald. Exophthalmic goitre, 342

Arms, position of in breech with extended legs, 320. See also Labour

ARMSTRONG, Captain Edward Randolph. Obituary notice of, 445, 481

ARMSTRONG, Richard R. Serological characters of disease-producing pneumococci, 259 (O)

ARMSTRONG-JONES Sir Robert. Use of alcohol in medicine, 609

ARMY, BRITISH

Advisory pay for officers on committees, 615

Army Dental Corps formed, 133

Black Sea army, 144

Defence force medical students in, 715

Hygiene in, 105

Parliamentary notes, 716

R A M C. Officers in India new rates of pay for, 406—Roll of Honour, 405—War Memorial, 536

R A M C. Fund. See Fund

Titles of retired officers, 699

The Week:

- Académie de Médecine centenary, 26
 Aethiopescopus abdominalis, 435
 Air ambulances 434
 Alcoholism. treatment of, 750
 Alexander and Parkes Memorial prizes, 96
 Alkaloids and glucosides, 59
 Ambulance plans, emergency, 616
 American Field Marshal (W. W. Keen), 279
 American Medical Association, 738
 Annual Meeting at Newcastle. Pathological Museum, 93—Programme, 535, 769—Revised arrangements, 679—Accommodation, 828
 Anthrax from shaving brushes, 207
 Apothecary poet (Keats), 905
 Army Dental Corps, 133
 Artificial limbs 436
 Asthma clinic, 615
 Benvenuto Cellini's medical experiences, 651
 Bilharzia disease 501
 Bilharziasis and its treatment, 650
 Birthdays honours 853
 Birth rate Commission on venereal disease, 314
 Births marriages, and deaths, 472

The Week (continued)

- Blackwater fever, 94
 Bright, Richard, his less known contributions to medicine 906
 Bright's disease, discoverer of, 573
 By-way of evolution, 867
 Calcutta School of Tropical Medicine, 574
 Cancer mortality, 512
 Cancer and the public, 472
 Cancer serum, 206
 Carbon monoxide, effects of on the eye, 649
 Cataclysmal haemorrhage after tonsillectomy, 397
 Cataract in iron workers, 906
 Census, the, 907
 Cerebro-spinal fever, studies in, 168
 Cervical defects, 59
 Chalmers A. J. memorial to 95
 Chemical industry, the fine, 133
 Children's dreams, 906
 Chinese honours for medical missionaries 208
 Chinese Red Cross Society, 615
 Cinema, the retarded, 359
 Cockroach, the, 614
 Comparative medicine, 356
 Condensed milk. *See* Milk
 Congress of medical history, 950
 Congress of military medicine 473
 Congress of radiology and physiotherapy, 205 393, 471
 Cremation in England, 236
 Cretins, photographs of, 574
 Croom, Sir Halliday, resignation of, 945
 Czechoslovak public health delegates, 273, 311
 Dehydrate rigidity in man 359
 Diabetes insipidus and the pituitary, 233
 Diphtheria carriers 27
 Disabled soldiers and the diamond industry, 358
 Dolling, Charles Edward, case of, 170
 Drugs Act, Dangerous, Regulations, 96, 240, 789
 Edward VI, the birth of, 788
 Efficiency on view, 279
 Encephalitis, lethargic. Outbreak of, 277, 357, and epidemic hiccuph 572
 Epidemic of unrest, 875
 Breast-eruption, 572
 Eyestrain in cinematograph halls, 231
 Fees of public vaccinators, 171
 Filariasis expedition, 280
 Fine chemical industry, 133 315
 Flavouring agents in medicines 27
 Food poisoning, outbreaks of, 170
 Friendly society support for hospitals 712
 Gardening for the blind, 680
 Gas supply, dangers of the domestic, 315
 Gastric ulcers. persistence of after perforation, 615
 Goats and goat's milk, 651
 Gorges memorial 615
 Harrogate waters, 749
 Hiccough, epidemic, 28; and encephalitis lethargica, 572
 Hill, Professor Edward, of Dublin 95
 Home ambulance service, 237
 Hospital almoners, 574
 Hospital for functional nervous disorders 680
 Hospital Inquiry Committee, 96 135 170
 Hospitals and the income tax, 631
 Hunter, Colonel William, C.B., 787
 Hydrocephalus in achondroplasia, 435
 Hygiene of seamen 538
 Ideals of a beloved physician, 947
 Immunity and industrial disease 827
 Index Medicus, new series, 614
 Industrial welfare and research, 435
 Industry, problems of, 748
 Infectious mononucleosis 95
 Influenza pandemic 1918-19 205
 Influential infection, experimental 94
 Institute of Physics, 679
 Insurance, National. Record cards, 59—Sanatorium benefit transfer of, 135
 International health work, 825
 Journal of Laryngology and Otology, 207
 Journal of Obstetrics and Gynaecology of the British Empire, 713
 Keen W. W. 84th birthday of 279
 Labour, teaching of the mechanism of, 213
 Langham Telephone Exchange, 573
 Laudes prize in tropical medicine, 823
 Lead nutritive value of, 501
 Laundry hygiene 714
 Lectures in London, advanced, 765
 Leptospira icterohaemorrhagiae experimental infection with 169
 Ligations of the left subclavian artery, 575
 Lighting, artificial, 711
 London University. Physiological laboratory of, 133, 206 273—site (Holland Park), 135
 London University, sixteenth century scheme for a, 58
 Lymphocytes fate of the, 905
 Lymphoblastosis acute benign 649
 Macdonald presentation fund, 206, 288
 Malaria in England 502
 Malaria prevention 238
 Manchester Radium Institute, 471
 Maternity and child welfare centres and day nurseries, 594
 Mayo Clinic, 631
 Measles, experimental, acquired immunity after 904

The Week (continued):

Measurement of human emotion, 280
 Meatless diets, 906
 Medical curriculum in Germany, 789
 Medical drainage of the biliary tract, 58
 Medical education in China, 313
 Medical History Congress, 950
 Medical Institute for Newcastle, 279
 Medical Insurance Agency, 788
 Medical Prime Minister, 826
 Medical scholarships for Serbian girls, 359
 Medical Society of London, 397
 Medical stores, surplus, disposal of to hospitals, 278, 828
 Medical students, instruction of in physics, 134
 Medical work in Kashmir, 714
 Medicinal herbs, 60
 Medicine of ancient Egypt, 472
 Medicine, history of, 750
 Mental therapeutics and the public, 948
 Midhurst Sanatorium, 650
 Milk, skimmed condensed, labelling of, 538
 Milk, pure and clean, 866
 Mitchell, S. Weir, 396
 Miners' housing, 539
 Mother, the unmarried, 749
 Motor fuel economy trials, 397
 Moulton, Lord, of Bank, death of, 433
 New year honours list, 58
 Obstetrical unit at the Royal Free Hospital, 714
 Ophthalmic work in Egypt, 503
 Ophthalmological Society's annual congress, 712
 Ophthalmology prize, 28
 Optophone, 574
 Ovaries, ablation of in mammary cancer, 615
 Oxford Ophthalmological Congress, 241, 949
 Parliamentary session, the new, 240, 280
 Pathological research applied to medicine, 616
 Pearl pathology, 827
 Pharmacology, clinical research in, 868
 Pharmacy, the future of, 948
 Physiology at South Kensington, 314
 Post-graduate Education Committee, 170
 Post-graduate instruction in Paris, 239
 Prince of Wales, 135
 Professional secrecy in courts of law, 904
 Psycho-analysis, quack, 133
 Psychotherapy, 168
 Public health in Czechoslovakia, 278, 311
 Public health officers, security of tenure for, 648
 Quack psycho-analysis, 133
 Radiological workers, protection of, 787, 947
 Radiology and Physiotherapy Congress, 205, 398, 471
 Radiology, research in, 536, 787
 Radio-therapeutics, research in, 787
 Rat extermination, 241
 Rats, ships, and crews' quarters, 866
 Reciprocity with South Africa, 949
 Red blood cells, diurnal changes in the size of, 239
 Red Cross, 713
 Red Cross Congress, International, 503, 537
 Red Cross war medal, 240
 Registrar-General's report for 1919, 169
 Research defence, 572
 Riviera in summer, 714
 Röntgen Society, 616
 R.A.M.C. war memorial, 536
 Royal Chest Hospital, 96
 Royal Naval Dental Service, 537
 Royal Society, 357—Conversazione, 748
 Royal Society of Medicine, 949
 Sanatorium benefit, transfer of, 135
 School punishments, 312
 Secret remedies and the German medical press, 649
 Serum diagnosis of syphilis, 950
 Service candidates, 682
 Silicosis and tuberculosis among miners, 26
 Small-pox, imported, 473
 Smoke abatement and the equipment of dwellings, 60
 Boyer, Alexis, 503
 Spelling of chemical terms, 539
 Spirochaetosis icterohaemorrhagica, 206
 Sport by artificial light, 867
 Strike, the: Emergency ambulance plans, 616
 Surplus medical stores, 278, 828
 Sussex provident scheme, 132
 Tell-tale treatment, 826
 Therapeutic substances not amenable to chemical analysis, control of, 357
 Thorburn, Sir William, 540
 Tropical medicine, Langley prize in, 828
 Trypanosomiasis research, 434
 Tuberculosis Bill, the new, 470
 Tuberculosis in the Canadian Forces, 680
 Tuberculosis conference, international, 398
 Tuberculosis treatment, 539
 Tumours as malformations, 789

The Week (continued):

Typhoid fever in the United States, 713
 Typhoid vaccination statistics, 651
 University of Bristol, 649
 Unmarried mother, 749
 Venereal disease, campaign against, 27
 Venereal Disease Conference, North European, 682, 749
 Vienna and London, 169
 Vitamin, 828
 Vitamines, 237
 War Emergency Fund, 28
 War finance of the Red Cross and St. John, 315
 War section of the Wellcome Museum, 314
 Women at Cambridge, 865
 Women on juries, 134
 Yellow fever investigations: In Mexico, 396; in Northern Peru, 436
 Weil's disease. *See* Spirochaetosis icterohaemorrhagica
 Wellcome Museum. *See* Museum
 WELLS, H. Gideon: *Chemical Pathology*, rev., 707
 WELLS, Sydney Russell, knighthood conferred upon, 865
 WELSH, Robert A.: Braille type for blind children, 179
 Welsh Board of Health (parliamentary note), 909
 Welsh National Memorial Association and tuberculous milk, 34
 WERNER, T. B.: "Aesthesioscopia abdominalis," 435

THE JOURNAL OF THE BRITISH MEDICAL ASSOCIATION.

EPITOME

OF

Current Medical Literature.

JANUARY TO JUNE, 1921.

London :

PRINTED AND PUBLISHED AT THE OFFICE OF THE BRITISH MEDICAL ASSOCIATION,
429, STRAND, W.C.

INDEX TO THE EPITOME FOR VOLUME I, 1921.

READERS in search of a particular subject will find it useful to bear in mind that the references are in several cases distributed under two or more separate but nearly synonymous headings—such, for instance, as Brain and Cerebral; Heart and Cardiac; Liver and Hepatic; Renal and Kidney; Cancer and Carcinoma, Epithelioma, Malignant Disease, New Growth, Sarcoma, etc.; Child and Infant; Bronchocele, Goitre, and Thyroid; Diabetes, Glycosuria and Sugar; Eye, Ophthalmia, and Vision, etc.

The Figures in this Index refer to the Number of the Paragraph, NOT the Page.

A

- AASI N. Diphtheritic heart and its treatment, 189
 Abdominal cavity, five year old foetus loose in, 189
 Abdominal hysterectomy for puerperal infections 92
 Abdominal operations local anaesthesia for, 121
 Abdominal wall, spontaneous haematomata of, 492
 ABELS Dentition and febrile processes, 230
 —Scorbutic dysentery, 382
 Abortion criminal air embolus after, 714
 Abortion, febrile cases of, treatment of, 467, 519
 Abortion missed 463
 Abortion and pre-mature labour, causes of, 635
 Abortion septic treatment of, 191 738
 Abortions repeated etiology of, 547
 ABRAMOFF Histology of the measles exanthem 310
 ABRAHAMSEN Thymoid extract in Köhler's disease 531
 Abscess of brain following wounds 328
 Abscess dissecting, of caecal wall, 147
 Abscess, abscond, pharyngeal suppuration secondary to 244
 Abscess, retropharyngeal, 677
 Abscess of tonsil, fatal case of, 331
 Acid, pepsin hydrochloric digestion of keloïds, cicatrices and buboes with 315
 Acne vulgaris, x ray treatment of, 617
 Acoustic nerve tumours 439
 Acriflavine irrigation in gonorrhoea, 512
 Acrobrachycephaly 43
 Actinomycel, radium therapy of, 203
 ADELUNG Pulmonary syphilis 426
 Adenitis in herpes zoster 6
 Adenitis, tuberculous, limitations of x ray treatment in 629
 Adenofibromata of the breast, 302
 Adenoma sebaceum and renal tumours, 393
 Adrenaline in ery thromelalgia 142
 Adrenaline and novocain injections in ery sipelas 621
 ADRIAN Arthropathies in scleroderma, 266
 —Africa, South psoriasis in 533
 Adrenoma cerebellar, 320
 AILSWORTH Digestion of keloïds cicatrices, and buboes with pepsin hydrochloric acid, 315
 AIEVOLT Torticollis 54
 Air embolus after criminal abortion 714
 ALAMANT Small mucous polyp of the corpus uteri as a cause of haemorrhage 574
 ALBRECHT Pregnancy and the thyroids, 62
 Alcoholism, chronic the corpus callosum in, 222
 ALKANDER Felinococcus disease of the lung and pneumothorax treatment, 357—
 Bronchial asthma 619
 ALKHAAN Treatment of nasal sinusitis 181
 Alimentary amenorrhoea, 445
 Alkaptonuria 579
 ALKASTO Relation of lethargic encephalitis to influenza 456
 Alveolectomy 559
 Amenorrhoea alimentary, 445
 .
 .
 .
 AMOS Serum treatment of acute poliomyelitis, 317
 Amyloid disease of the lung 556
 Ankytonia congenita 129
 Anemia, treated by nucleinate of manganese, 298
 Anemia of consumptives and intestinal tuberculosis 458
 Anemia pernicious, in childhood, 200—
 Treated by splenectomy, 403—And malaria 705
 Anemia, physiological, of pregnancy 218
 Anemia pseudo-leukaemic splenic, in infants, 613
 Anaerobic flora in intestinal diseases 193
 Anaesthetic treatment of the excitement attack 564
 Anaesthesia, continuous ether, during child birth, 573
 Anaesthesia local for abdominal operations 121
 Anaesthesia, spinal, action of on the hepatic and renal functions, 710

- Anæsthetic, a new (diethyl-l-diallyl) barbiturate of diethylammon 151
Anæsthesia lumbar 451
Anæsthesia rectal 241
Anæsthesia, effect of injections of sugar on, 327
Anæsthesia nitrous oxide oxygen death from, 628
Anaphylactic shock, prevention of 522
Anastomosis, spheno-femoral 411
ANDROIDS Glycosuria in pregnancy, 153—
The islands of Langerhans in diabetes, 222—
"Elephantia" fits in a case of chronic nephritis
after decapsulation of the kidneys, 661
Aneurysm of the hepatic artery, 211
Aneurysms of the cystic and splenic arteries, 614
Angioma of larynx, 332
Angina, Ludwig's, in a hæmophilic subject, 309
Angina Vincent's association of tonsillar
chancres with, 678
ANGIOMA of the nasal fossae, 19—
Morbidity anatomy of lethal encephalitis, 356
Anion, epidemic encephalitis at, 136
Antibody formation in leukaemia failure of, 367
Antisens partiel in treatment of surgical
tuberculosis 538
Antimony See Tartar emetic /
Antipneumococcus serum, 240
Antistaphylococcal vaccine in treatment of
osteomyelitis 47
ANTONY'S Infective processes in the teeth
and internal diseases 503
Anuria reflex calculus 178
Anus, malformations of 650
Aortic disease, disturbance of deglutition in,
45
Aortitis syphilitic, case of, 40
Appendicitis Diagnosis of, 272—Pain in the
left side in, 437—Simulated by acute anterior
polioencephalitis 510—Characteristics of in old
men, 431
Appendicitis chronic 410—Dyspeptic in sym-
ptoms due to 566
ARCANGLI Perforation in typhoid fever, 378
ARCADE Gland tubules in the Fallopian
tubes 187
ARIZZI Sachs Georgi reaction in syphilis,
449
ARLONG Neutrophile leucocytes in pul-
monary tuberculosis 255
ARRETRY Herpes zoster as the only sign of
latent disease 332
ARNOGOV Subcutaneous oedema in sero-
fibrinous pleuritis, 509
Aresenal paralysis due to neo-salvarsan, 73
Arsenobenzol splenomegaly due to 269
Arterial pulse wave, rate of propagation of, 720
Arteries cystic and splenic aneurysms of 614
Artero-sclerosis and dementia præcox 73
Artero sclerosis and chronic nephritis, hyper-
tension in, 63
Artery hepatic, aneurysm of 211
Arthritis acute in infants 507
Arthritis meningococcal, 369
Arthropathies in scleroderma 256
Artificial pneumothorax consecutive bi-
lateral, 139—Duration of, 645
Artificial pneumothorax in fractured ribs, 329
Artificial pneumothorax, pleural effusion in,
476, 477, 644
Artificial pneumothorax pleurisy with effu-
sion on the 'sound side in 644
Artificial pneumothorax in bilateral tuber-
culosis 646
Artificial pneumothorax in treatment of pul-
monary tuberculosis 209, 478
ASCOLI Irradiation of the hypophysis in
bronchial asthma 169
ASCOFARI Bilateral peripheral facial para-
lysis, 141
Asphyxia, fatal, from food block 274
Asthma, bronchial, 133, 619—Irradiation of
the hypophysis in, 169—Vaccine treatment
of 672
Astigmatism, influence of age upon 245
Astraculus removal of in paralytic feet 85
Athletics influence of on the heart 342
Auditory nerve tumours of, 326
AURI Insertion of the round ligaments and

- Anuric flinter and fibrillation in pregnancy, 658
 Aortic *Sre* also Heart and Cardiac
 Aortic War injuries and tuberculosis, 532
 Aortic Oesophageal stricture, 499

Measles: subcutaneous emphysema in, 379
Measles exanthem: histology of the, 310
Meckel's diverticulum: inflammation of, 21
Meconium: prognostic significance of the escape of, 216
... anterior cysts of, 612
... ion of massive doses
... gi reactions, 132
Melancon neonatorum: treated with horse serum, 255
Meningeal symptoms: in herpes of the anal region, 459
Meningitis: acute and tuberculous, 289
Meningitis: cerebro-spinal, purpura in, 106—A sign of, 459—Hydrocephalic form of in infants, 502
Meningitis: influenzal, indol in cerebro spinal fluid in, 252
Meningitis: and lumbar puncture, 104
Meningitis: acute otogenic, 270
Meningitis: purulent, in uterina, 673
Meningitis: chronic syphilitic, preceding tabes and general paralysis, 233
Meningitis: traumatic serous, in childhood, 355
Meningitis: tuberculous, 289, 316, 482—Curability of, 482
Meningococcal arthritis: 360
Meningococcal septicaemia: serum treatment of, 170
Meningococcal urethritis: 552
Meningococcus epidemic: in barracks, 311
Menopause: and opotherapy, 605
Menorrhagia: treatment of, 221
MINST: Paraisonic anaemia in childhood, 205
... Chloroma in infancy, 264
Menstruation: after ovariectomy, the cut-reaction during, 688
Mental activity: and smoking, 110
Mental forms: prolonged, of epidemic encephalitis, 670
Mental condition: in paralysis agitans, 381
Mental syndrome: a peculiar, following epidemic encephalitis, 668
Mercuric chloride: intravenous injections of for puerperal fever, 550
Mercuric chloride poisoning: unusual case of, 5
MERRIN: Meningococcal arthritis, 360
Mesenteric cysts: in infancy, 570
Methyl alcohol poisoning: 347
Methylene blue: polychrome, rapid preparation of, 102
MICHMANN: High forceps operation in contracted pelvis, 687
MIXER: Pneumococci in throats of normal persons, 32—Infectiousness of whooping-cough, 696
MIXERDING: Congenital torticollis, 630
MICHL: Surgical complications of typhus, 301
MICHON: The undescended testis, 584
Microchemical test: for ammonia, 36
Affersporon lanosum: causing outbreak of tinea tonsurans, 344
Myndleton: Pulmonary sclerosis, 560
Midwife: ... in, 126
Migraine: ... of frontal lobes, 46
MILIAN: ... of frontal lobes, 46
Milk injections: in puerperal infections, 281; in gonorrhoeal conjunctivitis, 465
Milk: subcutaneous injections of in treatment of mammary hypertrophy, 16

MINET: Gangrene of erectile tissue, 387—Vaccine treatment of asthma, 672
MINOZZINI: Experiments on temporary exclusion of one kidney, 275
MINALTI: The blood pressure and oedema in hemiplegia, 286
Mitral valve: congenital malformation of, 292
MOCOT: Acute necrosis of the pancreas, 115
MOERSC: Cerebellar agenesis, 320
Mole: hydatidiform, unusual case of, 94—In association with ovarian cysts, 155
Mole: tubal, calcified, 125
MÖLLER: Simple operation for prolapse of rectum in childhood, 557
MOLNAR: Meinicke and Sachs-Georgi reactions, 132
MONFRINI: Prognosis in syphilis, 41
Mongolism: observations on, 322, 698
MONOZZI: Protein therapy in pneumonia, 259
MOORE, Irwin: Angiomata of the larynx, 332
MOREAU: Incomplete fractures of scapula, 728—Direct fractures of calcaneum, 729
MORAV: Pharyngeal suppuration secondary to mastoid abscess, 244
MONOZO: Acute and tuberculous meningitis, 289
MORRIS: Hyperthyroidism, 428
Mortality: infantile, and premature birth, 471
MOSSARO: Oesophageal stricture treated by continuous dilatation, 657
MOTZFELDT: Starvation treatment of diabetes, 641
MOTCHET: Osteochondritis deformans juvenilis, 172—Fibrous osteitis and inherited syphilis, 176—Anterior dislocation of the os magnum, 541
MOGRO: Rate of propagation of the arterial pulse wave, 720
MOURE: Cutaneous cancer of the bridge of the nose, 537
MOURET: Congenital atresia and occlusion of the choanae, 626
MOUZON: Myasthenia gravis with osseous deviation in surgical

Mucosa: of laryngeal ventricle, eversion of, 545
MÜLLER: Enterostomy for post-operative ileus, 676
Mumps: treatment of orchitis in, 119
MUSZIN: Vascular sclerosis, 563
Murphy's button: causing intermittent intestinal obstruction, 151
MURRAY: Rupture of uterus in absence of cervical dilatation, 127—Fractures of the lower end of the radius, 489
Muscular exercise: changes in the heart and circulation due to, 265
Myasthenia gravis: with osseous changes, 173
Myososes: respiratory, 267
Myeloid leukaemia: treated with benzol, 432
... 726
... *See* Encephalitis of, 664
Myoma uteri: Late results of conservative operations for, 188—Operations for, 415
Myxoedema: the pituitary in, 593

A British Medical Association Lecture

ON THE

DIAGNOSTIC SIGNIFICANCE OF ABDOMINAL PAIN IN CHILDHOOD.*

BY

ROBERT HUTCHISON, M.D., F.R.C.P.,

PHYSICIAN TO THE LONDON HOSPITAL, AND TO THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND STREET.

ABDOMINAL pain in a child must always be a source of anxiety to the doctor. It may mean so little or so much. It may be due to nothing worse than an attack of acute indigestion set up by a green apple; or it may indicate an attack of acute peritonitis set up by a green and gangrenous appendix. It is a matter, therefore, which craves wary walking in diagnosis, for a mistake may be fatal, and between one's anxiety not to overlook a serious cause and one's natural reluctance to alarm the parents unduly it is often difficult to steer a proper course. Our difficulty in these cases is increased by the fact that pain may be the sole symptom of abdominal disease, and the little patient may be unable to help us, as an adult can, by describing its exact situation, character, and so forth, which are often so significant for diagnosis. It seemed, therefore, that we might profitably employ our time this afternoon by considering together the chief causes of abdominal pain in childhood, with a view to enabling us, when we meet such cases, to make a diagnosis by the method of exclusion if no other is available.

EXTRA-ABDOMINAL CAUSES OF PAIN.

At the outset it is well to remember that pain felt in the abdomen is not necessarily being caused there. In children, who localize their sensations badly, these extra-abdominal causes of pain are specially apt to lead to error. We may divide them according as the cause has its seat (1) in the abdominal wall, using that term in its widest sense, or (2) in the thorax.

1. Causes in the Abdominal Wall.

Spinal Caries.—Of causes situated in the abdominal wall this is one of the commonest. The pain in such cases is due, of course, to pressure on the posterior nerve roots, and is usually referred along the lower intercostal nerves to the epigastrium. It may come on quite early in the disease before any gross spinal deformity has shown itself, and the child will be brought to you under the belief that he is suffering from some abdominal trouble. It is well, therefore, to make it a rule carefully to examine the back in all cases of chronic epigastric pain in children. Slight prominence of one or more vertebral spines in the lower dorsal region can usually be detected, with tenderness on percussion over them and some stiffness on stooping. If in doubt, one can call in the help of the radiographer.

Lateral curvature in its more pronounced degrees is a similar source of error, but is less likely to be overlooked.

Rheumatism, or perhaps one should call it fibrositis, affecting the abdominal muscles, may easily simulate pain of intra-abdominal origin, and, like all rheumatic manifestations, is relatively common in childhood. It may be

met with either at the insertion of the muscles into the ribs or iliac crests or in the aponeurotic sheaths of the muscles themselves. The well-known "stitch in the side" which is common in children may, perhaps, be of this nature, but it is also met with in a chronic and protracted form. Fibrositis may be distinguished by the fact that the pain comes on when the affected muscle is thrown into action, as, for example, when the patient tries to sit up in bed without using the hands; there is often quite acute tenderness at certain parts of the abdominal wall, especially when the muscle is contracted, and if the abdomen is palpated in the ordinary way this may be mistaken for tenderness of an underlying organ. This error may be avoided by noting that tenderness is also elicited when the abdominal wall is grasped or compressed laterally. This form of pain is commonest in children of school age, and often follows hard exercise, and if the muscles of the right lower quadrant are involved appendicitis may be simulated. One sometimes wonders whether cases of so-called "rheumatic appendicitis" cured by salicylates are not really of this nature.

Herniae through the abdominal wall are not such a common cause of obscure chronic abdominal pain in the child as they are in the adult; but in the form of omental herniae especially they should always be thought of, and so should the possibility of an *undescended testis*.

Hip disease I have sometimes known to lead to error; not so much tuberculous hip disease as an acute inflammatory condition in or near the joint. This may cause pain referred to the lower part of the abdomen; there may be fever and the child may lie with the legs drawn up; and when the right hip is affected simulation of appendicitis may be fairly close. The limitation of movement in the joint which careful examination reveals ought, however, to keep one right.

Herpes zoster is the last of the causes in the abdominal wall which I shall mention. Pain in this affection may precede the appearance of the eruption by some hours or even days, and be of considerable severity; and I have known more than one instance in which it led to a diagnosis of acute abdominal disease. It can be distinguished by the fact that there is a band of superficial hyperaesthesia in the distribution of the affected nerve, that there is also severe pain behind, near the vertebral spines, and that deep tenderness on palpation or involuntary rigidity are absent. All doubts are dispelled before long by the appearance of the eruption.

2. Thoracic Causes.

The possibility of abdominal disease being simulated by acute intrathoracic conditions has been well recognized ever since attention was first directed to it by the late Mr. Barnard some years ago. Yet mistakes are still easy to make. The commonest form of error is to diagnose a case of pneumonia occurring at the right base as one of appendicitis. If the patient is a child, such an error is specially excusable, for in the child, more even than in the adult, the physical signs of a pneumonia may be entirely absent for some time after the disease has begun. Furthermore, vomiting is a very constant and conspicuous feature of early pneumonia in childhood, and helps still further to simulate the picture of abdominal disease. The abdominal pain in these cases is due, as you all know, to involvement of the lower intercostal nerves as they pass through the diaphragm, and in part also it may be a "referred pain." There is reason to believe that it only occurs when the diaphragmatic pleura is affected. Be this as it may, the

* Delivered before the South Midland Branch on July 8th, 1922.

combination of an acute onset, with fever, vomiting, pain referred to the lower abdomen, and some abdominal rigidity, coupled with an absence of the usual signs of pneumonia, may be deceptive in the highest degree. In attempting to make a diagnosis in such a case you will look for an alteration in the pulse-respiration ratio, though it is well to remember that the respiration is not always hurried at the onset of pneumonia in a child. You will note that the abdominal tenderness is superficial, and that there is no sign of pain on moderately firm deep palpation. You will also ascertain the presence or absence of tenderness in the recto-vesical pouch on examination by the rectum, although perhaps it is true to say that in the child this is more easily said than done. You will remember, also, that the higher the temperature the more likely is it that the case is one of pneumonia. In some cases you must remain in doubt, and then it is wise to stay your hand, and in a few hours, perhaps, the appearance of a pleuritic rub or a patch of dullness will make clear the nature of the disease.

Pericarditis, but apparently only when the diaphragmatic surface is involved, may also simulate abdominal disease, although it is much less common as a source of error than pleurisy or pneumonia. I remember a case of the sort which made a strong impression upon me at the time. The patient was a little boy, who was admitted to hospital under the belief that he had acute appendicitis. He looked very ill, lay with the knees drawn up and the abdomen rigid, complaining of pain which he referred to the hypogastrium. There was moderate fever, but an entire absence of other signs. I have forgotten whether he vomited. He was kept under observation for a few hours, and it was decided that if there were no more positive indications by the evening the abdomen should be opened. Just before the time agreed upon for this, however, a loud pericardial rub became audible, and the case subsequently ran the course of an ordinary rheumatic pericarditis.

INTRA-ABDOMINAL CAUSES OF PAIN.

Let us now pass on to consider the far more frequent cases in which the cause of pain is situated in the abdomen itself. We may divide these for the sake of convenience into (1) cases of sudden or catastrophic pain, and (2) cases of chronic or recurrent pain.

Sudden Catastrophic Pain.

By the "catastrophic" cases I mean those in which the pain sets in suddenly—"out of the blue" so to speak—and is of great intensity. They are the cases often spoken of as "abdominal catastrophes," and include many examples of what are known in surgical slang as "the acute abdomen." They are for the most part of surgical rather than medical interest, and I shall not say much about them except to point out as far as one can those in which immediate laparotomy is indicated.

At the outset it may be well to remind you that the possible causes of an abdominal catastrophe are far fewer in the child than in the adult. Children do not suffer from perforated gastric or duodenal ulcer, for instance, or from acute pancreatitis, and I can recall only one case of biliary colic in a child. The possibilities which one has chiefly to consider when confronted with a case of severe abdominal pain of sudden onset at this age are acute indigestion, appendicitis, and some form of acute intestinal obstruction, of which that due to intussusception is specially frequent in the child. Amongst the rarer causes one might perhaps mention abdominal or Henoch's purpura. Renal colic, which may also have to be considered, I shall have occasion to mention later on.

The immediate practical diagnostic problem in such a case is to eliminate *acute indigestion*. This is not always easy. The pain of acute indigestion may set in suddenly, may be of great severity, and may be attended by fever and considerable distress. Here is an example. A boy of 7, whilst convalescing from a mild attack of whooping-cough, was attacked by sudden abdominal pain of considerable severity, and in an hour or two his temperature had run up to 104°. He was restless and distressed, and begged that "something should be given him to relieve his pain." In view of the recent whooping-cough various diagnostic possibilities presented themselves, but soon one's doubts were solved by the copious vomiting of a quantity of undigested food, shortly after which he broke into a profuse sweat, and the temperature came down with

a run. If in doubt about such a case, the best course is not to pool-pool the whole affair as a mere stomach-ache and to give a dose of castor oil—still less an opiate—but to hold one's hand and wait. Meanwhile, there is no harm in giving an enema, and perhaps a mild emetic, and applying heat to the abdomen for relief of the pain.

The possibility of *appendicitis* is what will give you the most anxiety in these acute cases of pain. I shall not go into the diagnostic criteria in this matter in any detail, as they are much the same as hold good in the case of the adult; but I would only remind you that pain is the earliest symptom in appendicitis, that it is usually experienced first in the epigastrium, and only later settles into the right iliac fossa, and that it is rarely of great severity except in a very nervous child. Vomiting nearly always occurs, but it follows the pain and does not persist, as it does, for example, in cyclical vomiting; and although more or less fever is always present at some stage of the attack, it is rarely great in degree. In looking for muscular rigidity in children, light palpation is more important even than in the case of the adult.

Acute intestinal obstruction is nearly always attended by pain, which may be very severe, but I have seen cases of intussusception in which, at the outset at least, pain was entirely absent; probably they were cases in which there was an unusually long mesentery. The classical signs and symptoms of obstruction will be present in the child as in the adult, but it is well to remember that, owing to the tendency of the child to develop a temperature on slight provocation, some fever may be present even in purely obstructive cases, especially, perhaps, in intussusception. In the examination of these cases an anaesthetic is often of great help. It saved the situation in the case of a little boy whom I saw not long ago, who had been seized two days previously with severe abdominal pain. Other symptoms of intussusception were absent, but the abdomen was rather rigid and difficult to examine. He did not seem at all ill, and one was inclined to regard it as a case of colic, but under a whiff of chloroform the abdominal walls immediately relaxed, and a typical sausage-shaped tumour could then be felt running across the abdomen.

I have mentioned *abdominal purpura* as a possible cause of sudden acute pain. You will not expect to meet with this often, but as it is usually attended by haemorrhage from the bowel, it may simulate intussusception rather closely. A mistake may be avoided by careful examination for purpuric blotches in the skin, which are often to be found in such cases.

Chronic or Recurrent Pain.

When an adult complains of chronic pain in the abdomen the first organ one thinks of is the stomach. In the child, however, the stomach is rarely at fault in such circumstances. Children, I need hardly remind you, do not suffer from organic disease of the stomach, such as ulcer or carcinoma, and in them chronic or recurring abdominal pain usually has its seat of origin in the intestine. It is true that ordinary indigestion may cause some pain, probably from distension of the stomach with gas, but it is rarely severe in degree—rather a mere discomfort—and its definite relation to meals and its relief after the belching up of wind will usually make the nature of the case plain. The intestinal cases are, as I have said, far commoner, and we may divide them for convenience into those due to (a) ordinary colic, (b) "umbilical" colic, the meaning of which is to be explained immediately, (c) enterospasm, and (d) chronic obstruction.

(a) *Ordinary colic* is, of course, the commonest cause of abdominal pain in little babies, but it is met with also often enough in older children, and may contribute to the pain in those cases of acute indigestion of which I have already spoken. In the chronic or recurrent form it is more apt to appear as the variety known as "umbilical" colic, of which I shall speak presently. In whatever form it shows itself it is characteristic of colic that the pain occurs in spasms, that it is relieved by firm pressure—differing in this profoundly from the pain of appendicitis, for instance—and, what is of great diagnostic value if it is observed, that it is relieved, temporarily at least, by the expulsion of flatus from the bowel.

(b) The term "*umbilical*" colic was introduced by Professor Moro to designate a common group of cases, met with in children of school age, in which the patient

complaints of frequently recurring abdominal pain, which is always referred to the situation of the umbilicus. The pain may come on suddenly at any time in the day, but sometimes quite definitely after or during a meal. It may be severe whilst it lasts, even doubling the child up, and may be attended by sudden pallor. Vomiting is rare. The attack may last for only a moment or two or for a few hours, and there is sometimes a tendency for attacks to exhibit periodicity. As I have said, these cases are by no means uncommon, and every one who has done much outpatient work amongst children must be familiar with them, but their real nature is obscure. There are usually no objective signs of disease to be made out, and Moro was of opinion that the condition is a pure neurosis. I can hardly think this likely, and it seems more probable that we are dealing in these cases with a genuine colic in the large intestine occurring in rather constipated nervous children in whom perhaps the "gastro-colic" reflex is abnormally active—a condition closely akin to lenteric diarrhoea. Of the treatment of these cases, which is troublesome enough, there is no time to speak to-day, but their chief importance arises from the fear that in them one may really be dealing with "chronic appendicitis," but on that subject I shall have something to say in a moment.

(c) *Enterospasm* as a cause of abdominal pain is met with in children who are the subject of muco-membranous colitis. This is not infrequent in childhood, and when spasm of part of the colon occurs very severe pain may be produced. The contracted bowel may sometimes be felt, usually in the left iliac fossa, and the presence of mucus and membranes in the stools should make the diagnosis clear. It is worth remembering that muco-membranous colitis in children is sometimes attended by prolonged fever of considerable degree, and when attacks of enterospasm are superadded mistakes in diagnosis may easily occur.

(d) *Chronic intestinal obstruction* as a cause of abdominal pain is rare in childhood, and when it occurs is usually due either to compression of the bowel by a band, or a persistent Meckel's diverticulum, or to adhesions the result of old tuberculous peritonitis. The pain resembles that of colic in its nature, but there is usually some meteorism present, and visible coils of intestine may be seen. There is not necessarily any vomiting. The use of the x rays may help in the diagnosis if one is in doubt. The most difficult cases are those due to chronic intussusception, and in at least two instances of that condition I have known the true cause of the pain overlooked, even though the patient was for a long time under observation in hospital.

APPENDICULAR PAIN.

I now come to the most anxious cases of all—those, namely, in which the question arises whether a chronic or recurrent pain has its seat in a diseased appendix. There are some, I believe, who deny the existence of chronic appendicitis in childhood altogether. I think I have heard a surgeon say that a child either has acute appendicitis or the symptoms are not due to the appendix at all. Most of you will probably agree that this is an extreme view, but at the same time I am sure that one ought to be extremely cautious in diagnosing chronic appendicitis in children, especially when the pain is confined to the right side of the abdomen. On the other hand, it is probably nearer the truth to say that disease in the appendix in the child is never chronic from the beginning, there is always a preceding acute or subacute attack. In making a diagnosis, therefore, a history of such attacks should be inquired into with great care. They will usually be described as "bilious attacks," but if they were attended by pain, some vomiting, and fever, and were bad enough on any occasion to confine the child to bed, one should be very suspicious. Physical examination in cases of chronic or relapsing appendicitis between attacks may be entirely negative, and I do not think that the use of x rays affords much help. One must often be in doubt between chronic appendicitis and "umbilical colic," but if there is a clear history of "bilious attacks," and if the parents, as so often happens, are worried about the state of the appendix, then I think it is best to advise exploration, although it is unwise to guarantee any result from the operation other than the relief of the parental mind.

Worms are often believed by parents to be a cause of abdominal pain in childhood, but my own experience

would not bear this out. Round worms are those which would be most likely to produce the symptoms, for they are sometimes numerous enough even to produce intestinal obstruction. A vermifuge will soon settle the diagnosis.

Enlarged glands. On the other hand, are, I believe, a much commoner cause of abdominal pain in children than is generally realized. I do not mean necessarily tuberculous glands, but a simple enlargement of the glands at the lower end of the mesentery. These often become infected in cases of appendicitis in children, just as the glands at the angles of the jaw do in tonsillitis. I saw a very striking example of this not long ago in the case of a boy who was suddenly attacked with pain, vomiting, and fever. He presented the signs of appendicitis, but there was a curious tumour about the size of a walnut to be felt in the right iliac fossa which was certainly not the appendix. At operation it proved to be a mass of acutely inflamed glands, the appendix being also inflamed and its mucous membrane ulcerated. There is often no history of any acute disease in these cases of chronic enlargement of glands, though no doubt they must have been infected from the caecum or appendix; but, once enlarged, they are apt to cause pain in the right lower quadrant, possibly by dragging upon or kinking the bowel. At all events they are often the only thing found wrong in children on whom an exploratory operation has been performed for suspected chronic appendicitis, and their removal is usually followed by disappearance of the attacks of pain.

CAUSES IN THE URINARY TRACT.

Affections of the urinary tract are a frequent and often overlooked cause of abdominal pain in early life, just as they are in the adult, although some conditions which are relatively common in grown-up persons are rare in the child. Movable kidney, for example, though it is occasionally met with in children, need hardly be thought of as a cause of pain. Attacks of true renal colic also are not often exhibited in the child, though gravel is perhaps a not uncommon cause of pain in babies. On the other hand, there are two conditions which are certainly more frequently sources of abdominal pain in the child than is generally realized: one is *kinking of the ureter* and the other is *ureteric calculus*.

Kinking of the ureter results, as you know, from a congenital abnormality in the distribution of the renal blood vessels. As a rule it does not produce symptoms until early adult life, but I believe that it would be diagnosed oftener in the child if it were looked for. It is one of the causes of so-called "bilious attacks." I had once a very striking example of this in the case of a boy of 15, who was alleged to have suffered since his early childhood from attacks of abdominal pain and vomiting which recurred every few weeks with great regularity. They had been diagnosed as "bilious attacks." I happened to see him in an attack. He referred the pain to the left loin, and an enlarged and slightly tender kidney could easily be felt on palpation. Surgical investigation established the presence of kinking of the ureter, and a greatly disorganized kidney was subsequently removed. These cases are deceptive because of the regular periodicity of the pain and the entire absence of any urinary symptoms.

Ureteric Calculus.—Just as the symptoms of a kinked ureter are apt to be diagnosed as "bilious attacks" so the symptoms of a ureteric calculus, when it occurs in the right side, are usually attributed to "chronic appendix mischief," and indeed the simulation may be very close. There may be a history of attacks of right-sided spasmodic pain; there may be a rise of temperature and tenderness over the ureter (which is very close to McBurney's point), and urinary symptoms may be absent. The moral is that a radiograph of the ureteric region should always be taken before an operation is performed in quest of a supposed diseased appendix.

In the male *urethral obstruction* as a result of phimosis or a narrow meatus may cause attacks of hypogastric pain from over-distension of the bladder, but the association between the pain and the difficulty of micturition is usually obvious, and the vesical tumour easily made out. In girls, on the other hand, one has sometimes to think of *pelvic causes* such as salpingitis, but I mention these rather for the sake of completeness than because I regard them as common causes of abdominal pain in childhood.

A Clinical Lecture

ON

EPILEPSY CONSIDERED AS A SYMPTOM,
NOT A DISEASE.

BY

JAMES TAYLOR, C.B.E., M.A., M.D., F.R.C.P.,

PHYSICIAN TO THE NATIONAL HOSPITAL FOR THE PARALYSED AND
EPILEPTIC, QUEEN SQUARE; CONSULTING PHYSICIAN TO
MOOREHEADS EYE HOSPITAL AND TO THE QUEEN'S
HOSPITAL FOR CHILDREN.

So much has been written about epilepsy from the earliest times that it may seem presumptuous in anyone to think or hope that he may contribute something new to such a subject. I should make no such claim, for I feel sure that much of what I am about to say has been said before, although it may have been said differently, and the subject may have been approached from a somewhat different angle. I have been fortunate enough to have a considerable experience of this disease, if disease it is to be called, during a good many years, and I have been not a little disappointed and surprised at the tendency which has lately become obvious towards an attempt to approach its explanation on other grounds than that of physical disturbance—in my opinion, a definitely retrograde movement.

In a recent paper¹ Dr. Pierce Clark, apparently despairing of any physical interpretation of epileptic phenomena and curiously oblivious of the constant tendency in Hughlings Jackson's writings, sets himself to explain them on a psychological basis. Such a psychological basis for phenomena of which the physical symptoms are so distinct, requires much ingenuity and not a little imagination. It seems to me that it would be just as reasonable to require a psychological basis for Jacksonian fits, or for uraemic convulsions, or for the convulsions produced in a monkey by the intravenous injection of absinthe, as for the phenomena of what has been called epilepsy. With regard to the so-called "latent phenomena" of epilepsy we frankly have no belief in them. We happen to know men (and women too) subject to occasional convulsive attacks, who on ordinary occasions are normal healthy individuals, working regularly, doing good work, capable intellectually and physically, in whom the most earnest psychological analyst or observer would fail, we feel sure, to detect any abnormality. And to say that "transitory phobias, ecstasies, and most common of all, irritable and depressive states," are characteristic of latent epilepsy, is to make statements which any physician is able out of even a limited experience, to contradict explicitly. Even of so-called advanced cases of epilepsy—by which we understand is meant cases subject to recurrent convulsions during many years—to say that these are characterized by "ethical depravity of the entire personality" is to state what in the experience of many of us is not correct. Every physician knows that such "ethical depravity" is not uncommon as a degenerative sign without any tendency to convulsion; and what is spoken of as an "egocentric contraction of the entire emotional life," characterized by pathological lying, etc., is certainly not symptomatic of, or confined to, patients who are the unfortunate subjects of repeated convulsions.

Dr. Pierce Clark says he undertook a study of the "character make-up" in a small series of "essential epileptics" before they had their first attack. It would be interesting to know whether this study was really made before the first attack or was an afterthought. If it was made before the first attack one would like to know the basis for his belief that attacks were coming; if it was made after the attacks were established then of course it loses any little value it might have had. He says he found "nothing wanting in the complete picture of the character as seen in those suffering from a long enduring and severe epilepsy." He also remarks on the different attitudes of "trained clinicians" in epileptic colonies and physicians in private practice. He seems to deny the title of "trained clinicians" to physicians in practice. Does he not think that the so-called "trained clinician" in an epileptic colony is much more likely to be biased in his views than is a man who is at least equally well trained, and much more widely experienced in varied forms of disease? He even

claims that the colony physician has a much broader view of the whole problem, which, of course, is absurd, seeing that he is dealing with advanced and apparently incurable cases, and has no experience (or ignores it) of patients subject to occasional attacks who are able to get about, to do good work, and of whose tendency to occasional attacks everyone, except their immediate relations and their physician, is in complete ignorance. The colony physician surely has a narrow and restricted view of these phenomena because his patients are of a class only suitable for institutional treatment—for, as the author confesses, the institutional physician "receives the most badly deteriorated patients." It is quite beside the mark to say these are "fearfully handicapped by drug and surgical treatment." The point to be recognized is that as a class they are deteriorated. But it does not at all follow that the numerous patients subject to occasional convulsion—many of them active and useful and energetic members of society—are to be regarded as the subjects of the same psychical condition as those institutional inmates.

With special reference to Dr. Pierce Clark's assumption that there is something in the so-called "psychological make up" of patients usually called epileptic, I will now mention briefly some cases which have come under my own observation which to my mind afford clear evidence that patients who have suffered from these so-called epileptic fits have no signs of either physical or mental deterioration.

The first case is that of a healthy-looking man of 50, who consulted me some years ago on account of several convulsions occurring in the previous year. He was an energetic business man, busily engaged in the control of a large and important business in which he had been unusually successful. The history was that at the age of 17 he had had an attack in every way similar to those for which he consulted me. He was put on simple treatment, his activities, mental and physical—he was a keen lawn tennis player and golfer, as well as an active business man—were in no way interfered with, and he went on well. Soon after I saw him he was elected Provost of an important town in Scotland, and the duties of this office—extremely exacting throughout his years of office during the war—were carried out in such a way as to earn him praise from everyone, and recognition in the highest quarters. He still pursues his active business career and is in every respect a healthy man. He has entirely left off medicinal treatment.

The next case is that of a young man of excellent physique, who two years before the war had on successive days two generalized convulsions. He was put on medical treatment, which was continued in gradually decreasing doses for two years. There was no recurrence of any kind, and he served in the army during several years of the war. He is, and has been since he was demobilized, actively engaged in an extremely responsible position in a business house, and has remained quite well.

The next case also is that of a young man—a hospital patient, engaged in electrical work, who for some years had been subject to recurrent convulsions, with loss of consciousness. He had been compelled by the frequency of these to give up his work, and treatment at first only succeeded in abating the frequency and severity of the attacks. Persistence in treatment, however, was finally successful in completely controlling them, and for over a year now he has been free from attacks, and has been actively engaged in his somewhat arduous and responsible work.

The next case was certainly at first sight not a promising one—a lady between 50 and 60, who had been subject for many years to convulsive attacks, with loss of consciousness. These occurred at varying intervals—sometimes of months, occasionally of days—and there were also occasional minor attacks. Treatment on rational lines in her case was also successful, and she has now been for over a year free from attacks, living the ordinary social life of a lady of good position, and occupying herself much in good works.

The last case I shall mention is that of a lad whom I saw five years ago, who had then had only a few attacks, always in the morning after getting up. He had one or two after treatment was commenced, but none in the last two years, and he is now actively engaged in study at one of the universities.

I could mention other cases, but these will suffice to emphasize the point I wish to make, namely, that patients who have been the victims of attacks—even if these have been spread over a good many years—do not necessarily deteriorate either physically or mentally. I may mention that in all these cases bromide has been the “sheet anchor” in treatment, but this, like other drugs, must be used with intelligence and discrimination both in regard to dose and mode of administration. Of course, no one with any experience of these cases of convulsion can think of denying that there are cases—unfortunately not a small class—in which treatment is inefficient, and in which the convulsions persist in spite of all one's efforts at treatment. These we must assume are cases in which degenerative processes are superadded to some local disturbance, or cases in which the local disturbance is so situated or is of such a nature as to lead to such changes. But it seems to me unreasonable to suppose that such cases are the result of anything but physical changes.

I think that in the past we have given far too much attention to those cases of generalized recurrent convulsions to which the name of epilepsy has been applied, and too little attention to those cases of localized or Jacksonian attacks which were also described by BICATIS. For I believe it is by a study of these and of their relation to the cases of so called ordinary epilepsy that any real step forward in the elucidation of the nature of these ordinary cases, and in their treatment, is to be looked for.

Although I was under the impression that I had arrived at this belief independently, I have little doubt that I must have imbibed the substance of it from Dr. Hughlings Jackson's teaching. For I have recently found that so long ago as 1874 he wrote as follows:

‘I have long been convinced that ‘idiopathic epilepsy’ is far too difficult a subject for precise investigation unless we approach its consideration from the bases supplied by the principles deduced from the less complex kinds of cases.”

Again he says:

“Epilepsy like aphasia has been studied with a psychological habit of mind, and, as I think, this way of studying such a disease is unfruitful.”

Let us now consider for a moment these cases of localized or Jacksonian fits. These fits are recognized as the result of changes occurring locally in the brain giving rise to signs of irritation in the peripheral structures, motor or sensory, related to the unstable brain area.

We need not consider now the nature or cause of the irritability. It may, of course, be various. A certain part of the brain is irritated, movement is produced in a peripheral part and may remain restricted to this, or the movement may spread so as to affect all parts of the body, and also affect consciousness, this being the result of a spread of irritation from an unstable area to normal structures. In other words, the convulsion may become general—an Jacksonian fit may become a general convulsion—the convulsion may start as the result of irritability in some unstable cells but the irritability may spread from this focus or fulminating area and cause discharge in structures which are quite healthy and normal. It is not uncommon for a patient subject to Jacksonian attacks to suffer from attacks of varying degree. On one occasion the convulsion may affect only a finger and thumb, on another occasion it may spread to affect a whole limb, or on still another the convulsion may affect the whole body, and if this happens, consciousness is almost always if not invariably, lost. If the convulsion is a purely local one, consciousness is nearly always returned and not infrequently a local convulsion is prevented from spreading by firm pressure on, or pulling of, the limb proximal to the part already in a state of movement. Many such cases have been published, and the evidence is familiar to all students of this disease. In such a case we are justified in assuming that there is some local condition—it may be mechanical, it may conceivably be chemical or nutritional, rendering a few cells unstable and inducing in them a tendency to the discharge of nervous energy, and the instability of these cells may, unless it is by some means prevented, as by some strong effect on the peripheral structure, induce in contiguous healthy cells a similar instability and tendency to the discharge of nervous impulses. If this spreads widely enough a general convulsion may result.

As an illustration of what I have here said I may

mention the case of a patient seen with Dr. Farwell and Dr. Spon, and subsequently by Mr. Percy Sargent. The patient was a healthy man who had for some time suffered from fits, some slight without any loss of consciousness, others more severe with general convulsion and loss of consciousness. All the fits, whether slight or severe, started with a sensation and subsequent movement in the right lower limb. Sometimes the convulsive movement affected only this limb and consciousness was not lost. In others the movement spread from this limb and became generalized, and consciousness was lost. It was obvious that in this case the focus of irritation was in what is known as the leg area of the left hemisphere, an area near the middle line. There was no headache and no optic neuritis, but the condition was regarded as probably the result of the irritation caused by a tumour growing in or from the meninges in this region, and Mr. Sargent was able to remove a growth of a non malignant character from the situation in which it was possible to foretell its presence. I have purposely refrained from overburdening this brief account of this case with details which are unnecessary for our present purpose, which is to show that local irritation may give rise to only a local disturbance in the peripheral parts—a Jacksonian fit—or may result in a general convulsion commencing locally. I may mention that although the fits in this case occurred once or twice after the operation, and although there was some subsequent weakness of the affected side, the fits have now been absent for some years.

There is a class of patients consideration of the cases of whom is very instructive from the point of view of local irritation causing fits. I refer to cases of so called infantile an inflammatory condition of the spinal cord causing infantile identical in origin. The initial character is by violent convulsion, feverishness, etc. The convulsions in such cases commence unilaterally, and during the acute stage become general, and there is not infrequently a condition of real *status epilepticus*. If the patient recovers, the resulting condition is one of hemiplegia, sometimes very severe, sometimes very slight, and in after life there is a liability to the occurrence of convulsions, sometimes only unilateral of the affected side of the body, sometimes spreading from such a commencement to become general.

I might here digress for a moment to recall the fact that besides the severe general convulsion with tonic and clonic spasms—*grand* or *haut mal*—which occur in so called idiopathic epilepsy, there are also conditions of *petit mal* in which there may be only momentary loss of consciousness without convulsion. I now proceed to relate a case which was under my care and observation for some years—that of a woman of 25 with a definite history of convulsions occurring in early life in the course of a feverish attack, and resulting in slight right sided weakness. The hemiplegia, it was supposed, passed off, but there was still slight right sided weakness. The patient was left handed, but was able to write with the right hand, and the condition was obviously one of very slight right hemiplegia dating from early life, and apparently the result of an attack of polio encephalitis of the left hemisphere. She consulted me on account of her liability to occasional “fits,” apparently general convulsions, starting in the right hand. But even more troublesome than the attacks or severe convulsions, which did not occur very often, were attacks of *petit mal* of frequent occurrence, and often followed by a condition of ‘automatism’ in which apparently purposeful acts were carried out quite unconsciously.

Such attacks of *petit mal* with automatism are supposed to be characteristic of so called essential or idiopathic epilepsy, and I would urge that a case such as that which I have just related is somewhat strong presumptive evidence that such a condition of *petit mal* is probably in other cases associated with actual structural changes in the brain, just as it certainly was in the case I have related. I do not here refer to the explanation of the automatism.

Dr. Hughlings Jackson was, I believe, the first to direct our attention to an exceedingly interesting class of cases, in which the chief symptoms were a curious aura of ‘reminiscence,’ also spoken of as the ‘intellectual aura’ or dreamy state, in which the patient seems to be passing through a familiar experience so that he almost knows what is coming next, and this is usually, although

not invariably, associated with a curious but indescribable, often disagreeable, smell. To such cases Dr. Jackson applied the name "uncinate epilepsy," because in some cases in which such an aura was associated with convulsions, or at least with loss of consciousness, a lesion was found in the uncinate gyrus of the temporo-sphenoidal lobe.

In some cases the lesion was a tumour, in one case a small non-malignant cyst. In the case¹ in which the cyst was found by Dr. Walter S. Colman the patient was a medical man who had been subject for many years to recurrent attacks ushered in with the "dreamy state." In this case the cyst was probably the result of some early, probably vascular, lesion, the effect of which was to produce a small area of unstable cells in that particular region. Here was a case characterized by recurrent convulsions of a particular kind, only differing from other cases of so-called idiopathic epilepsy in the character of the aura which preceded a fit. We know that in some of these cases the convulsion is associated with a structural change in a certain part of the brain. It is only reasonable to conclude that in all of them this same area is unstable—the cause of the instability in many is not proved—but the presumption is that in all the cause is a structural derangement.

There is another class of cases in which the convulsion is preceded by a visual aura. In some of these the aura is a somewhat elaborate one—a little woman in a red cape or some equally definite vision. In many the visual sensation preceding a fit is a simple one of flashes of light, and this causes the convulsion. In one case, which I have related elsewhere, the fits were left-sided, preceded by an indefinite disturbance of vision. These fits had come on rather suddenly and unexpectedly in an old lady sent to me by Mr. Fisher, and they were associated with definite homonymous hemianopia. The fits gradually ceased, the hemianopia persisting but gradually and completely disappearing. This lady made a complete recovery, and remained well for several years. In such a case one is justified in assuming that there was some vascular lesion—in the occipital cortex—which was at first irritative, but when the irritability of the cortex had subsided or been controlled resulted in temporary interference with the functions of the area in the cortex subserving the fields of vision of the opposite side. Such a case suggests that in cases with similar visual phenomena associated with fits the fits are due to some disturbance in the same area, and the fact that the convulsions are recurrent merely shows that the irritation is a persistent one, and not transitory, as in the case just related.

There is another class of cases that have to be considered—those, namely, in which attacks may have been present for years, associated with convulsion and loss of consciousness, but yet in which no sign of gross disease has been discoverable. I have elsewhere related two cases of this nature—one a patient who had been attending at the National Hospital, Queen Square, for seventeen years suffering from recurrent convulsions, but who unexpectedly developed headache, and was found to have optic neuritis. This patient died, and was found to have a large cerebral tumour. Another patient was under my own care, and had been attending for four years on account of occasional convulsion with loss of consciousness. He had no headache and no optic neuritis, and his convulsions were few in number under treatment; but he suddenly found himself suffering from severe headache, and the headaches became so severe that optic neuritis, and the headaches became so severe that decompression was undertaken with the hope of relieving him. There was intense intracranial pressure, and he died after a few weeks, and a large growth was found in one hemisphere. These two cases are, I believe, examples of a group—not perhaps a very large one—but they illustrate the thesis, so far at least as such a group is concerned, that such cases—apparently for years cases of so-called idiopathic epilepsy—are really cases in which early slight structural changes are almost certainly the cause of the fits.

It is well known to all who are interested in cases of recurrent convulsion, and who see many patients suffering from these, that there is a large class of cases in which the fits occur only during the night, so it is said, and these cases are named "nocturnal epilepsy." I think most observers will agree with me that it is not the time of day which determines the onset of convulsion in these cases, but the condition of sleep, for it is not uncommon for a

patient who suffers from such convulsions to have a fit during the day if he happens to fall asleep. So that it is sleep that really determines the attack, and the presumption is that it is some condition of nutrition or circulation associated with sleep which gives rise in certain cells to discharge which results in a convulsion. What the actual condition is we need not at present inquire. It is sufficient for our present purpose to note the fact.

In another class of cases the fits always occur in the early morning while the patient is dressing. In one case the fits only occurred if the patient had an early cold bath, and always occurred in the bathroom. In such a case it would seem as if the change of posture from the recumbent during the night to the upright in the early morning was the determining cause, and it seems natural to presume that the accompanying modification of the circulation was sufficient to give rise to the conditions determining a discharge in unstable cells.

Such considerations as those I have set out and the study of cases of a nature similar to those I have mentioned seem to me to indicate clearly that epilepsy should not be regarded as a disease but as a symptom. The convulsions of what is called epilepsy are not in their manifestations to be distinguished from the convulsions of uraemia or from those occurring with heart-block and in other conditions. It is only the discovery of associated conditions which reveals the true nature of the convulsions, and the more one sees of these convulsions in what is called ordinary epilepsy the more is one driven to the acceptance of Hughlings Jackson's dictum that "there is no such thing as a case of ordinary epilepsy."

Each case of recurring convulsion must be studied by itself. The origin of the convulsions, their nature, the march of the discharge, and especially any premonition or "warning," must be most carefully considered. By such study the cause of the convulsions is most likely to be revealed, and if this is disclosed, treatment, either surgical or medical, may be undertaken with some hope of success.

An Address

ON

THE HOUR-GLASS STOMACH.*

(With Special Plate.)

BY

C. THURSTAN HOLLAND, M.R.C.S., ETC.,
LECTURER ON RADIOLOGY, UNIVERSITY OF LIVERPOOL.

A DESCRIPTION of this well-known condition—hour-glass stomach—is hardly necessary, and in its typical form the x-ray picture is dramatic to a degree (Fig. 1). The picture of such a typical condition, after a test barium meal, shows the upper sac or cardiac end full of the food, and the lower end of this shadow has a clear cut margin, which as a rule comes down below the level of the narrowed outlet. At the site of the outlet on the lesser curvature is the ulcer cavity, with its lower part full of the food and with a gas bubble above it. A narrow stream of food passes downwards into the lower sac. This lower sac is half filled or more than half filled with food, and in this lower part, as watched on the x-ray screen, normal stomach contractions are seen and food going through the pylorus. This is the typical picture, but its x-ray varieties are very numerous, and scarcely any two cases are exactly alike in all their details. I have a record of 151 cases in which radiography showed an hour-glass condition of the stomach following on a test meal. An analysis of these cases brings out certain facts and shows certain fallacies and the possibilities of errors. The many variations which occur will depend upon, for the most part:

1. The size of the upper sac.
2. The size of the constriction.
3. Whether or not an actual ulcer cavity exists and fills up with food, and, if so, its shape and size, and whether there are adhesions to neighbouring organs and tissues.

* Given before the Manchester Medical Society, November 1920.

FALLACIES AND POSSIBLE ERRORS.

If the definite typical appearances are seen no possibility of error presents itself, and the diagnosis is certain. In less typical cases, however, there are certain possibilities of error which must be reckoned with and guarded against. I will allude to a few of the more common possibilities.

1. *Gastroplois*.—In this condition the stomach may be much elongated; food on entering collects in the cardiac end, extends downwards in a straight or more or less thin line, and then fills up the lower portion of the stomach. The appearance of an hour-glass constriction is thus simulated by the drawing out, and so drawing together, of the central portion of the stomach surfaces. However, no error of diagnosis should arise in this condition, since (1) the pressing up of the food from the lower part by the hand when viewed on the screen, and (2) the examination of the patient in the lying down position, will at once obviate any possibility of making a mistake.

2. *Malignant disease* will not unfrequently give rise to appearances simulating hour-glass constriction from old simple ulcer; but as a rule this disease causes other alterations in the shape of the shadows which will at once give rise to suspicion. Additionally the history of the case—the more rapid onset of symptoms—rapid loss of weight, and so on will indicate the real nature of the case.

3. *Pressure from Distended Large Bowel*.—A large collection of gas in the splenic flexure or its neighbourhood pressing into the greater curvature of the stomach will occasionally (1) cause the food shadow to simulate an hour-glass constriction, or (2) may mask a real hour-glass stomach. If this gaseous distension—easily recognized on an x ray plate—is seen, the bowel should be again cleared out and a second examination made. This, and the screen appearances seen on pressing food upwards from the lower part of the stomach, easily leads to the differentiation. (Figs. 7 and 8.)

4. *A Small Ulcer on the Lesser Curvature and Spasm*.—These may be considered together. The former may set up spasmodic contraction, or spasmodic contraction may be present alone without any definite stomach lesion. In the latter case it is as a rule associated with bad teeth, the appendix, gall-bladder trouble, duodenal mischief, or more remotely the pancreas. These spasmodic contractions are always atypical. They differ entirely from the appearances seen in the typical case described. Both causes give rise to a definite drawing in of the greater curvature, which, at any rate for a time, will sharply divide the stomach shadow into two well-marked portions—an upper and a lower sac. (Figs. 9 and 10.)

Sometimes a true hour-glass constriction will give rise to the same x ray appearance and take this form of a sharp drawing in of the greater curvature on quite a small area, and it is this true hour-glass stomach which has to be differentiated from the pseudo-type. (Fig. 11.)

To do this, and when this appearance is seen, very great care must be taken. Sometimes massage of the stomach will relax a spasm and clear up the diagnosis. Sometimes pressing the food in the lower part upwards will open a spasm up and prove that the constriction is temporary. If any further doubt exists, a second test meal on a future date may show the absence of any constriction. Examination in the lying-down position, the administration of belladonna, and so on, may be of help. At the same time, if we have to deal with an ulcer of the stomach which gives rise to spasm that simulates a true hour-glass constriction, then the results as regards the symptoms of the patient and the treatment required will in reality be the same. The obstruction is there and potential, whether it be due to spasm or a definite cicatricial narrowing. I emphasize the point—when an ulcer is actually present—if the spasm is due to reflex causes then its effect on symptoms will vary according to whether it is present or not, and of course no operation on the stomach itself is indicated.

SEX OCCURRENCE.

It is a very remarkable fact that—at any rate, in my experience—true hour-glass constriction from old ulcer

occurs with far greater frequency in females than in males. In my whole series of 151 cases it occurred in females in 123 cases and in males in 23, but many of the males on analysis should not be classified as hour-glass constrictions of the stomach, due to simple ulcer—a point I shall refer to later on—and in a few of the females also this is the case. This means that the total number of true cases is less than 151.

It is a very curious point—I cannot offer any likely suggestions as to its cause—that, taking out all those cases in which there can be no doubt about the condition—namely, those cases of hour-glass contraction undoubtedly due to simple, as contrasted with those due to malignant, disease—and the huge majority of these are in females. This fact in males is seen so unfrequently that it may almost be said to be rare. Perhaps there may be some connexion in the wearing of and pressure from corsets, but I am not very satisfied with this as an explanation.

Analysing the males in more detail, I find that—

1. Although nine of them presented an hour-glass appearance, either clinically, under the x rays, or at operation, or by all three methods, they were in reality cases of definite malignant disease. In all these cases the history—and I take it that this is a point of great importance—was a very short one, extending over months only.

2. Five were cases in which a gastro-enterostomy had been done some years previously, and these appeared to be due to the late effects of the gastro-enterostomy.

3. One followed on a very severe abdominal crush. Therefore only 8 out of the 23 males can be classified as typical hour-glass stomach caused by simple ulcer—and of these 5 were proved by a later operation. The history of these cases was the same as that in the females—the salient point being that symptoms had been present over a number of years, extending from a few years up to, in one case, twenty years.

As a considerable number of the cases occurred during the war, complete records are unobtainable, but I have the records of 73 operations, and it seems to me that this number is enough to establish the important points.

In two of these cases only (both females) was it decided by the surgeon at the operation that there was malignant disease, and they were closed up without anything being done. (Fig. 12.)

In two cases (Mr. Thomas) at the operation enlarged glands were present, and the cases on the table were considered to be probably malignant. In both the operation was proceeded with, and a removed gland was later reported on as being "simple." The after-history of one case is not known; the other is known to have been alive and in good health six years later.

In the remaining 69 cases, at the operation nothing was found to give rise to any suspicion of malignant disease. Many—again I regret that I cannot supply exact figures—have been seen again so long afterwards that malignant disease was out of the question. I have not any record that it is known that in a single case any later suspicions of malignant disease have arisen.

Referring in detail to a few of the more interesting cases which came under observation: In one at the operation a constriction two to three inches long was found; there was no evidence of any old ulcer except some very slight cicatricial tissue along the lesser curvature. This was a female, aged 31 years, with a history of attacks of pain and vomiting for ten years. There were no adhesions; the food came away from the upper sac from its lowest point in a thin stream corresponding to the size of the constriction, which hardly admitted a small probe. This is possibly a case of congenital hour glass stomach. A second case showed two distinct ulcer cavities on the lesser curvature. Another case showed all the food in what was obviously the upper, cardiac, end of the stomach; a thin stream tended to percolate downwards; no ulcer cavity and no lower sac was made out. The history was that eight weeks previously she had swallowed a wineglassful of oxalic acid; no doubt the lower part of the stomach had been practically destroyed. A fourth case must be one of the rarest possible occurrence: a woman of 40 years of age, the usual prolonged history of digestive disturbances, but also associated with acute colic attacks in the left abdomen just below the costal margin. It was discovered that she had transposition of viscera, which an x ray examination showed to be complete—the stomach was on

the right side and the colon transposed. She had a typical hour-glass constriction from an ulcer on the lesser curvature.

At the subsequent operation Mr. Kelly confirmed the x-ray findings absolutely, but he also found a collection of gall stones in a gall bladder on the left side. It is unfortunate that we had not examined her for gall stones—they might have shown. The combination of transposition of the viscera, plus hour-glass stomach from ulcer, and plus gall stones, must be one of the rarest pathological conditions ever reported.

FREQUENCY OF THIS CONDITION.

It is obvious from the number of cases I alone can report that it is a comparatively common condition—151 cases spread over a period of ten years in the x-ray department of one hospital, in which only in-patients are examined as regards the stomach, prove this. Before the days of x-rays it was looked upon as comparatively rare.

DIAGNOSIS.

The exact demonstration of this condition must be looked upon as one of the many triumphs of radiography—a triumph almost, if not quite, as fine as the demonstration of kidney and ureter stones. It is not too much to say that the accurate diagnosis is entirely one of radiography, and a consideration of the symptoms, etc., and their bearing on the case, prove this to the hilt. At the same time, of course, too much must not be expected by the surgeon, and in many points of detail it may fail to indicate certain features found at operation.

If we take into consideration the main features of a case, the difficulty—or even the impossibility—of accurate clinical diagnosis becomes evident. In its classical form you have a stomach with an ulcer of long standing somewhere about its middle, and usually on the lesser curvature. This ulcer is frequently of the slow penetrative type, and it becomes adherent to liver, pancreas, or other neighbouring structures. As a result of cicatrization the stomach, at the site of its occurrence, is so narrowed that there is a stenosis, and the food passes through the stenosed portion with more or less difficulty, according to the amount of the stenosis, or according to the amount of the stenosis plus some additional spasm. The latter—spasm—is of purely secondary consideration, as, if it is present, its effective action is precisely the same as a permanent cicatricial stenosis. Now, if you have an ulcer at or near the pylorus causing pyloric constriction, exactly the same potentials are present, except that the food block in the latter condition is at the pylorus instead of in the body of the stomach, and the only essential difference is the passage of the food from the stomach into the bowel instead of from one part of the stomach into the other.

The point is that the ulcer will give rise to the same symptoms in whichever place it occurs if it produces a stenosis, and you will get precisely the same history from the patient—namely, a very long history of attacks of indigestion usually associated with pain after food relieved by the vomiting of food. Sometimes there is vomiting of blood—we have a record of this in 51 of the cases only. The attacks get worse and worse, the intervals between are less and less free from indigestion, and then an attack which persists for a long time without relief, often with considerable loss of weight—due to malnutrition and inability to take food—and the patient is finally x-rayed and the diagnosis made clear.

The history, the physical signs, the condition of the patient, will not, in the vast majority of the cases, distinguish between pyloric stenosis from ulcer and the hour-glass constriction from ulcer.

We used to hear much of the importance of gurgling on palpation—caused by pressing the fluid contents from one sac to the other—and of obtaining sour and stinking stomach contents by means of washing out, and so on, and it was said that these were diagnostic signs. To my mind they are of little or no importance, and they will not be obtained in the huge majority of the cases, but only in those cases in which hour-glass constriction and pyloric stenosis are present in the same case.

It is rare to find that the upper sac does not (1) allow its contents to pass on even if slowly, and it often empties quite rapidly, or (2) that it will eject its contents after an interval by vomiting. It is also rare to find pyloric

stenosis associated with hour-glass stomach, although I have seen this on occasion; and when it does occur it can almost always be determined by the x-ray examination.

I say, therefore, that the clinical diagnosis is always one of extreme difficulty, and as a rule one can go even further and say that it is practically impossible. The diagnosis is an x-ray one, and, always admitting limitations as to detail, it is extraordinarily accurate.

I have taken a note as to the provisional diagnoses entered on the papers which are sent to the x-ray department when an x-ray examination is asked for. They include dilated stomach, pyloric stenosis, gastric spasm, gastric ulcer, malignant disease, oesophageal stricture, visceroptosis, intestinal obstruction, and, lastly, "cause of symptoms" and "no diagnosis"—the latter is undoubtedly the safest. In only five cases of the whole series has hour-glass been mentioned on the papers sent with patients to the x-ray department and the diagnosis been confirmed by the x-ray examination. On the other hand, when first these cases began to turn up somewhat frequently in the x-ray department, we got a number of papers marked "hour-glass stomach," and in practically none of these was the condition found.

I am not making these statements in order to criticize in any way the ability of many accomplished physicians and diagnosticians, but merely to emphasize my point—namely, that the exact diagnosis is almost an impossibility, and that the distinction between hour-glass contraction and pyloric stenosis cannot as a rule be made.

Simple Ulcer and Carcinoma.

The final point I wish to raise is the bearing of these records on the much vexed question of the cause of gastric carcinoma and their bearing on the probability of simple ulcer being a frequent predisposing cause of stomach cancer. It must be, of course, understood that I am speaking entirely from the limited experience of the x-ray department and the impressions which the x-ray examinations have made.*

Examination of the records of 151 cases of hour-glass contraction, in which it may be taken that the large majority were caused by gastric ulcer, yields the following results:—

We must eliminate cases definitely proved before operation to be due to causes which do not come within the scope of this paper; we must eliminate also 9 of the male cases in which, although they presented an hour-glass appearance, the diagnosis was one of malignant disease, and in which the histories were so short that there was no reason whatever for supposing them to be cases of long standing; they were obviously recent malignant disease with no previous symptoms. We come then to this: That we have some 120 females and 8 males in whom an hour-glass contraction existed and in whom the history extended over years, and of these cases 73 females and 5 males can be recorded with their operative findings. Five of the females had a history of less than one year; all the males and the rest of the females had histories of anything from two to thirty years, the longer histories largely predominating.

In these cases, as I have said before, the typical history is repeated attacks of acute indigestion plus pain and plus vomiting, and in less than half a history of haematemesis; a long history of gastric ulcer, mostly of a type in which there is obviously the greatest possible amount of local irritation due to a chronic ulcer over which food is constantly passing, and in many cases an ulcer cavity adherent to, and its walls partly made up of, neighbouring tissues. If ulcer is the usual predisposing cause of gastric cancer, then surely this is the very type of case in which it should occur frequently. Yet what do we find? In 128 cases (120 females and 8 males) only one female and two males were proved to have cancer, and in all 73 operations recorded, and with 3 on the operating table thought to be malignant, but whom the later history or the pathological report proved them to be not.

Again, and from the x-ray point of view, we see a large number of huge, dilated atonic stomachs due to pyloric stenosis, and without being able to give you the actual figures, I am sure that in our department they are equally frequent in men and women. The history is again one of many years' duration; the cause is practically always pyloric ulcer. So few of these are afterwards reported as

* See *Liverpool Medico-Chirurgical Journal*, January, 1914, p. 107.

showing any evidence of malignant disease that, although in an occasional case malignant disease is reported as having been found at the operation, it is so rarely that I have come to look upon these cases as so certainly non malignant as to warrant an optimistic pre operative prognosis.

On the other hand, an x ray experience of the malignant stomach is that it is far more frequently seen in males; that on going into the history carefully, the very large majority state that the symptoms have been present for a matter of a few months only; and that never in their lives have they had any "indigestion" before this attack. There is nothing in the history to suggest in any way a pre-existing ulcer. I say that this is the common history, and that only a comparatively few relate a long continued history of intermittent attacks of digestive disturbance.

There are also other facts bearing on this question. Duodenal ulcers are extremely common; they are continually irritated; they are rarely malignant. Cancer of the oesophagus is so common that I have seen literally hundreds of cases in the x ray department. The symptoms are sudden and the history almost invariably that of a few months at the most—nothing to suggest previous ulcer.

These facts have produced a very distinct impression and raised very great doubts in one's mind that gastric ulcer is a common antecedent to malignant disease of the stomach. I suggest that these x ray facts will require a lot of explanation before such a cause for cancer of the stomach can be accepted in the vast majority of cases.

Summary.

1. Hour-glass contraction from simple ulcer is a comparatively common condition—frequent in females, rare in males.
2. Its symptomatic history is a long one.
3. It is almost entirely an x ray diagnosis.
4. It rarely ends in malignant disease—especially in females.
5. An hour glass condition is found in a few cases, mostly in males, and with a short history, and which is caused by malignant disease. Its x ray appearances generally differ considerably from those seen in the non-malignant type, and are suggestive.
6. The experiences of a large x ray department are strongly opposed to the theory that it is usual for cancer of the stomach to be preceded by a simple ulcer.

MESSAGE OF THE HEART AND RESUSCITATION.

BY

J. A. GUNN, M.D., D.Sc.,

PROFESSOR OF PHARMACOLOGY IN THE UNIVERSITY OF OXFORD.

IN a paper published in this JOURNAL (November 6th, 1920) Mr. W. E. Fisher describes cases of "Resuscitation in Death under Anaesthesia," and in regard to cardiac massage he says that "it will be of great help if an understanding of the processes concerned is quickened by a clear pronouncement by physiologists, to whom we must look for guidance and more definite directions." I feel sure that he is not aware of a paper published in 1915¹ by P. A. Martin and myself, in which we attempted to give clearer directions for performing cardiac massage than had hitherto been done, and anticipated some of the observations that he has made on the human heart. Since this paper has escaped the attention of others who have subsequently written upon the subject of cardiac massage—as is almost inevitable with the multiplicity of medical journals—I think one may be excused for recapitulating, in a journal more accessible to clinicians, some of the results there recorded, the more so as I may take this opportunity of adding some other observations on the subject of resuscitation based upon unpublished experiments.

I may first state part of the conclusions arrived at by Martin and myself.

"In performing massage of the arrested heart with a view to reviving the spontaneous contractions, the following points are of importance:

"Compression should be gradual and relaxation abrupt. The rate of compression should be at most less than half the normal

heart rate. Massage should be regularly interrupted at short intervals for a few seconds to allow the spontaneous beats to develop. When the heart is arrested, massage, properly performed, acts both as an artificial circulation and as a mechanical stimulus to the heart muscle.

"Massage can be performed in the following ways, arranged in order of efficacy: (1) By direct compression of the heart through an opening in the thoracic wall; (2) by compression of the heart above the diaphragm through an opening in the abdominal wall; (3) by simple compression of the abdomen; (4) by simple compression of the thorax.

"Direct thoracic massage combined with intrapericardial injection of adrenaline can revive the heart in practically any case of chloroform poisoning in the rabbit, even though the treatment be not begun until fifteen minutes or more after the heart has completely ceased to beat.

"In about 70 per cent. of cases recovery can be obtained if treatment is commenced ten minutes after arrest of the heart by the following procedure: artificial respiration through a tube in the trachea; intrapericardial injection of adrenaline; massage through an opening in the abdomen. If, when the heart has been started, the blood pressure continues low and the heart beats remain (chiefly as a consequence of this) feeble, speedy and permanent improvement of the heart and blood pressure can be obtained by intravenous injection of either adrenaline or pituitrin.

"Treatment on these lines is suggested for cardiac arrest in the human subject, occurring either in chloroform poisoning or in other conditions in which general recovery might be anticipated to result from resuscitation of the heart."

Before the publication of our paper the expression "massage of the heart" had been used as if the manner of performing it were indifferent, but we found experimentally that attention to points of detail may make all the difference between success and failure in difficult cases of resuscitation of the arrested heart. The grounds for certain of the conclusions given above may therefore be of value.

One question of the first importance is this, that "rhythmic compression of the heart effects in the first place an artificial circulation; it produces movement of the blood in the vessels to an extent which depends upon the way in which it is done." In animal experiments such as we performed an indication of the mechanical efficiency of massage in effecting a circulation of the blood could be obtained (the blood pressure being at zero) by the amplitude of the wave of blood propelled into the aorta by each compression of the heart. A record of this wave was obtained by a mercury manometer connected with a carotid artery. But a more direct proof of the fact that massage of the heart acts, to begin with, as a substitute for the spontaneously beating heart in causing a circulation of the blood was obtained in the following way. A solution of a blue green dye "was injected into the cavity of the right ventricle of an arrested heart. Cardiac massage was then performed, and after a few compressions the blue green colour appeared first in the lungs and then in the carotid artery. Massage had therefore propelled the blood from the right ventricle through the lungs and left side of the heart into the systemic circulation."

Fisher describes this action of massage as "an influence upon the circulation that I have not seen previously observed." It is all the more interesting that he has described independent observations on the same phenomenon but judged by different effects—namely, flushing of the skin and rise of intraocular tension occurring as the result of massage prior to spontaneous beating of the heart.

This action of massage has an importance not merely academic. I have started the heart beating an hour after it has been arrested by chloroform. I have performed the evoked heart of a stillborn child four hours after the child was born, and started the heart beating again. The difficulty is not so much in starting the heart, though this may of course be difficult, but in starting the heart sufficiently soon that the other tissues have not meantime been rendered incapable of recovery by stoppage of the circulation. So far as is known, it is the cells of the central nervous system that are most susceptible to stoppage of the circulation, so that, from the practical point of view, the circulation must be started before the cells of the central nervous system are irretrievably damaged. The current opinion is that after complete stoppage of the circulation for about fifteen minutes the cortical cells cannot be revived. While my own experiments have also pointed to this conclusion, I am not convinced that it is true; and, for reasons that I need not enter into here, I should not be surprised if some day it were shown that even the cortical cells can survive arrest of the circulation for a much longer period. What is

known is that they are difficult to revive. It is not proved that they are dead.

Many other tissues can withstand absence of circulation for a long period. Thus I have revived the movements of the isolated guinea-pig's uterus after seven days' keeping in cold storage, and the human Fallopian tube after thirty hours;² the rabbit's intestine after five days;³ the human vermiform appendix after thirty-six hours;⁴ and the heart after twenty-four hours⁵ or longer. At higher temperatures they do not survive so long,⁶ but even at temperatures between ordinary room temperature and body temperature they survive for hours. In tissues such as these there need be no anxiety in regard to the possibility of restoring their functioning capacity after prolonged arrest of the circulation. The liver requires further investigation.

In the meantime the question of resuscitation may be taken to depend upon how long the cortical cells can survive arrest of the circulation. And it is in this connexion that there arises the importance of the capacity of cardiac massage to act as an artificial circulation. For the difference between complete and incomplete stoppage of the circulation is enormous when gauged by the effects on the cells of the central nervous system. It has been found, for example, that when an attempt has been made to occlude the cerebral circulation by clamping the vessels to the brain, much more prolonged survival of these cells may occur if a mere trickle of blood through a small vessel be intentionally or accidentally left. Other phenomena point to the same conclusion. For example, in hibernating animals both circulation and respiration are reduced to a very low level for months, and yet the animals revive rapidly and completely when the circulation and temperature, etc., are restored. Now the experiments by Martin and myself are confirmed by Fisher's observations, and it can be taken as proved that massage of an arrested heart, if properly performed, can act as a fairly effective mechanical means of conducting an actual circulation of the blood. This being so, it is more than probable that, for the purpose of deciding whether the cells of the central nervous system are capable of complete restoration or not, the time can be calculated not as from the start of spontaneous heart beats but as from the time of beginning massage. This is a point of fundamental importance, and puts a different and more hopeful complexion upon the whole question of resuscitation.

Method and Rate of Compressing the Heart.

In the paper already quoted we said further:

"Judged merely from the point of view of its acting as an artificial circulation, massage would be most efficacious when carried out uninterruptedly, because the maximum amount of circulation of blood would thereby be accomplished, and therefore the speediest elimination of chloroform. However, we have repeatedly found that this is not the case, the reason being that this procedure fails to take due cognizance of the second function of massage—that, namely, of acting as a mechanical stimulus to the heart itself. The latter is the real object aimed at in performing massage; and, though a mechanical circulation may be a necessary preliminary to obtaining conditions under which the heart can resume its action, it is clear that, even from the point of view of circulating the blood, cardiac massage is an inadequate substitute for the beating heart. It is essential that this mechanical stimulation should be applied in such a way as most effectively to encourage the spontaneous contractions of the heart. This is not attained by continuous massage. It has been found, for example, that massage which has started feeble spontaneous beats, if continued without intermission, may cause the beats to disappear again. No doubt it is possible to overdo mechanical stimulation, and continuous massage does not give the heart a sufficient opportunity of developing spontaneous beating. We have found, as a result of a large number of experiments, that when the feeblest beats have begun, even beats which fail to move the manometer, it is better to cease massage for some seconds so as to allow them to develop, and to apply short periods of massage intermittently, when it is usually found that perhaps by the third or fourth series the heart suddenly regains a normal rhythm and the blood pressure rises rapidly."¹

The most effective rate of compression is much slower than the normal heart rate, for two reasons: One is that a slow rate is necessary to allow complete filling of the ventricles, and the other that it is a subnormal rate of beat that one is attempting to elicit—namely, the rate at which the arrested heart will begin beating again. The advantage of intermitting massage had not previously been suggested. Possibly if attention were paid to this,

attempts to revive the human heart would be more successful.

Action of Adrenalin.

There is no known drug comparable with adrenalin in efficacy to start an arrested heart or to antagonize the action of chloroform. I have shown that adrenalin can start beats in a perfused mammalian heart—for example, when kept for twenty-four hours—when mere perfusion has failed. When the isolated mammalian heart is perfused with concentrations of chloroform or chloral which almost or even completely arrest the heart, the addition of adrenalin to the chloroform or chloral solution is able to restore the heart beats to their normal vigour.⁵ This is an extraordinary effect. It is not an antagonism of the type, for example, of atropine versus pilocarpine. For chloroform and chloral depress the heart muscle, and in the experiments referred to adrenalin is able to antagonize a concentration of chloroform or chloral which practically or completely stops the heart while the latter solution is still passing through the heart, and its action therefore getting deeper. I do not think that this power of adrenalin—which is equivalent to stimulation of the sympathetic nerve of the heart—to antagonize a muscular paralysis has been sufficiently realized.

When the circulation is arrested in the intact animal, the difficulty, of course, is to get the adrenalin at the heart, even intravenous injection being practically useless when the heart has stopped. One method is to inject adrenalin into the pericardial sac before beginning massage, but this might be difficult to one who has had no experience of giving such an injection, and I have myself no experience of performing it in man.

Seeing, however, that massage causes an artificial circulation, adrenalin will reach the heart in time from a vein if massage be continued. This will occur sooner the nearer to the heart the vein is into which the adrenalin is injected. If it were injected into an external jugular vein it would very probably reach the arrested heart after a few effective compressions by massage.

One point in regard to adrenalin which may cause confusion is that a combination of adrenalin and chloroform is, as has been pointed out by Levy, more likely to produce fibrillation of the heart than chloroform alone. This, however, refers only to cardiac arrest from chloroform occurring in the initial stages of anaesthesia. This danger does not occur, in my opinion, in cardiac arrest occurring at other times.

There is another point in regard to the action of adrenalin about which there seems to be a good deal of misconception, and that is as to the permanence of its effect. It is true that in the normal animal with a good blood pressure the rise of blood pressure produced by adrenalin is very transient, lasting only a few minutes. But this is not true in certain abnormal conditions of the circulation—for example, when the animal is being resuscitated after arrest of the heart. Here the blood pressure may remain low after spontaneous beats of the heart have begun. This low blood pressure is due partly to temporary paralysis of the vasomotor centre and partly to feebleness of the heart's contractions. These two effects interact on one another. This vicious circle is broken by adrenalin. The temporary rise of blood pressure provides a better blood supply to both heart and vasomotor centre, and this may be sufficient to enable both to function properly, and in these circumstances the rise of blood pressure produced by adrenalin may be permanent. I believe it may be so in other similar conditions of the circulation.

Figs. 1 and 2 are reproduced (by permission) from the paper referred to. They show the sequence of events in a difficult case of restoration of the heart after it had been arrested by chloroform, and massage begun fifteen minutes later. The effects of intermittent massage are shown and the permanent effects of adrenalin injection.

Artificial Respiration in Man.

I have taught my students for years that the time will come when every hospital will be provided with an appliance for mechanically performing artificial respiration in man. So far this prophecy has remained unfulfilled. The usual method employed in the laboratory for this purpose in the case of laboratory animals is a pump or bellows which forces air into the trachea, and so distends the

lungs. It is a method theoretically imperfect, which in practice works well and gives no trouble. I have seen it stated in physiological textbooks that this method of performing artificial respiration is inadmissible in man, but I have not seen any convincing evidence given for this statement. In the case of adults with very rigid chest walls there would be theoretical objections to it, but, with the patient in the horizontal position, very probably an excursion of the lung sufficient to give the minimum necessary aeration of blood could be obtained by that expansion of the lung allowed by little else than movement of the diaphragm. If necessary, oxygen could be used instead of

tube. It was this method that I used in resuscitation experiments on rabbits.

If the heart has stopped, for example, in the course of chloroform anaesthesia, to get the heart started again is only the beginning of resuscitation. The next thing is to get the natural respiration evoked. Now when the circulation has been stopped for several minutes, the respiration does not commence immediately upon the heart beginning to beat again. It takes time for the respiratory centre to recover. In animal experiments I have seen thirty minutes elapse between the starting of the spontaneous heart beats by massage and the beginning of

FIG. 1.

FIG. 1—Rabbit. Heart arrested by chloroform. Showing complete resuscitation. Manometer record of blood pressure, and pulse wave in carotid artery. The periods of massage are marked. By the end of Fig. (b) feeble spontaneous beats had commenced, and by the end of (c) the heart was beating regularly. Blood pressure remained low. Intravenous injection of adrenine produced an abrupt rise of pressure (d). The pressor effect was maintained (e, taken twenty minutes later).

air. But, in any case, in children the method of positive artificial respiration ought to prove just as serviceable as in animals like the dog.

Having in view the possible adoption of this method of performing artificial respiration in man in cases of resuscitation, etc., I have modified the usual technique in order to dispense with tracheotomy and the time involved in performing it. Instead of tying a short cannula into the trachea through a tracheotomy opening, a long tube is passed through the mouth and larynx down to just above the bifurcation of the bronchi. This tube should be of about two thirds of the internal diameter of the trachea. When intermittent positive artificial respiration is used—for example, by a Brodie's pump—each blast distends the lung and the air escapes along the outside of the tracheal

natural respiration. More usually it is between five and ten minutes. If artificial respiration is not carried on during this interval, the heart will of course fail again from asphyxia. It is therefore imperative that artificial respiration should be kept up after the heart has begun beating again and until normal respiration begins.

There is no question that the problem of resuscitation is enormously facilitated by the employment of mechanical artificial respiration. With an apparatus such as Brodie's respiration pump with its modern improvements, whereby the amount of air pumped and the rate of pumping can be altered at will, and the air warmed or charged with a volatile anaesthetic if desired, one has no anxiety with regard to the respiration. Artificial respiration can be intermitted and restarted in a moment. If it be found

possible to use this method in man—and I shall be convinced of the impossibility only when I see it fail—there would be a great increase in the percentage of recoveries after attempted resuscitation in man.

Other Factors requiring Attention in Resuscitation.

In experiments which I performed in the latter part of 1915 I found that there were certain other points which have an important influence on the speed and completeness of resuscitation, and which I may take this opportunity of pointing out.

In the first place, when natural respiration begins (after arrest of the heart, massage, etc.) the respirations to begin with are slow. When the tube through which artificial respiration has been performed is allowed to remain in the trachea they tend to continue slow. I found on looking over the data of experiments that when this tube was removed from the trachea there was invariably a sudden and pronounced increase in the rate of respiration. This, no doubt, was partly due to increase in the available lumen of the trachea consequent upon the removal of the tube. But it seemed greater than could be accounted for by that alone, so that it is possible that the presence of the tube, from reflex irritation of the air passage, tends to slow the natural respiration. Whatever the theoretical explanation the practical conclusion is clear: As soon as natural respiration has become established the tracheal tube should be removed.

In the second place, there is one danger point in the course of resuscitation which I believe is of great importance and which has not to my knowledge been noted before. After considerable experience in resuscitating animals killed by chloroform, I found that I could anticipate with some confidence that I would be able to resuscitate an animal, by the methods described, to the stage that the heart beats and natural respiration were resumed. But here an unexpected difficulty arose, because I found repeatedly, but not invariably, that after the first gasp or two of natural respiration the heart, hitherto beating well, suddenly ceased beating and could not be restored even by massage. I had this experience with three rabbits in succession in one day. This was distinctly disappointing. In casting about for an explanation the only one that suggested itself—and it is not entirely satisfactory—is this: After stoppage of the circulation for several minutes the central nervous system is paralysed. The centres recover when the circulation is resumed and the blood aerated. When the respiratory centre recovers, probably other medullary centres recover somewhere about the same time. It is conceivable that when the respiratory centre commences to function the vagus centre commences at the same time or only just later, and that after its prolonged abeyance of function there is a sudden and excessive discharge of vagal impulse which stops the heart. Acting on this hypothesis, whether it be correct or not, in subsequent experiments I gave an intravenous injection of atropine to prevent vagal inhibition, and after that I did not experience this type of cardiac failure. The result may, as so often happens, have been due to an increase in skill in performing the experiments of which I was not cognisant. But in any case, seeing that atropine can do no harm, I think it would be advisable provisionally to adopt this safeguard in resuscitation in man.

Lastly, in all resuscitation experiments great care must be taken to maintain the body temperature. After stoppage of the circulation and temporary paralysis of the whole central nervous system, the animal does not easily recover its power of heat regulation.

SUMMARY.

To sum up, I would venture to lay down the following directions for resuscitation in cardiac arrest in man or animals, whether from chloroform anaesthesia or from any other condition in which cardiac arrest is "accidental."

If the heart has stopped, artificial respiration should be resorted to immediately by the usual methods. If, at the end of three or four minutes, no pulse can be felt, and especially if no heart beats can be heard on auscultation, adrenalin should be injected into an external jugular vein, by an assistant if available; if no assistant be available, I believe the gain from adrenalin more than compensates for the loss of time, provided the materials are at hand, as they ought to be. In the meantime, or subsequently,

as the case may be, the abdomen should be opened high up, one hand inserted in the opening, passed up over the left lobe of the liver, and the heart felt for above the diaphragm. The heart should then be massaged intermittently. I endorse all that Mr. Fisher says in regard to not relying upon artificial respiration alone and in regard to boldness of procedure if the heart has stopped. When it has stopped there can be no further risk. As soon as spontaneous beats of the heart, however feeble, are felt massage should be interrupted for several beats to allow the contractions to establish themselves; otherwise, continuous massage may abolish them again. The heart should then be massaged again for a short time, when the beats will probably improve. When the heart has begun beating it is safer to use too little than too much massage. The hand should not be removed from the abdomen till the heart is beating well. When the heart continues to beat regularly and strongly an intravenous injection of atropine should be given. Artificial respiration must be kept up continuously, also after the heart begins beating. After five minutes it may be interrupted to see if natural respiration will begin, but not for long. No harm is done by keeping up artificial respiration, even if it inhibits the natural respirations, whereas, on the other hand, it is not safe to interrupt artificial respiration very long, if natural respiration does not commence.

If it be found that positive artificial respiration can be used in man by, for example, a Brodie's pump of larger size than that used in the physiological laboratory, the problem of resuscitation will be greatly facilitated.

Natural respiration may be expected to begin in five to ten minutes after the heart begins to beat again, but may be delayed for thirty minutes.

During the manipulations, and afterwards if these procedures be successful, care must be taken to maintain the body temperature.

All attempts, successful or not, at resuscitation after cardiac arrest in man should in the present state of knowledge be recorded. When it is possible—and it cannot well be possible unless assistance is available—accurate notes should be kept not merely of the sequence of events, but of the actual times of occurrence.

THE PRACTICAL GAINS OF CLINICAL CARDIOLOGY SINCE 1900.*

BY

W. GORDON, M.A., M.D., F.R.C.P.,

PHYSICIAN TO THE ROYAL DEVON AND EXETER HOSPITAL; PHYSICIAN TO THE WEST OF ENGLAND EYE INFIRMARY.

DURING the last twenty years a great deal of interesting and valuable work has been done in medical cardiology. What I propose is briefly to summarize the practical gains which we, as clinicians, have derived from it. In so limiting my field, I am forced to exclude from it much that is interesting, as belonging to physiology rather than to medicine. But I hope that what my paper thus loses in attractiveness it may atone for by usefulness.

CARDIOLOGY IN 1900.

I need hardly remind an audience well read in the literature of twenty years ago that all the factors involved in cardiac failure were then clearly recognized; that no one called in question so obvious a truism as that the cardiac muscle was of predominant importance; or doubted the danger of such mechanical impediments as a leaking aortic orifice or a contracting mitral. No thoughtful person then referred to "back pressure" as a cause of heart failure, but only as a consequence and complication of it. Gaskell's brilliant work had shown that the heart muscle was more independent of nervous control than had previously been imagined, and Kent and Ellis had demonstrated the path along which the normal stimuli of contraction travelled. The effects of vascular disease, in and

* Read at a meeting of the Devon and Exeter Medico-Chirurgical Society, to open a discussion, December 16th, 1920.

outside of the heart, were then fully recognized, as were also the injurious consequences of anaemia. The influence of the endocrine glands had begun to be investigated. Poisons, organic and inorganic, of bacterial or other origin, were attracting the attention they deserved. Overstress had been discussed. Malformations had been elaborately described. The infections of the endocardium were being enumerated. It was fully recognized that many irregularities of the pulse were of little consequence, and that some murmurs mattered, whilst others did not. Thus murmurs were divided into "functional" and "organic," and amongst these latter the decided differences in seriousness were carefully indicated; the minor significance of irregular pulse in childhood had not been overlooked, intermissions were usually held to need no treatment, and "delirium cordis" was regarded as a special indication for digitalis—although it must be noted that in mitral stenosis the continued administration of the drug was often found badly borne. Our excellent existing classification of cardiac diseases had been already built up and almost all our present remedies were in familiar use.

OUR GAINS SINCE.

I will divide my material into the following sections: Treatment, prognosis, diagnosis, physical signs (detached for convenience), and etiology.

TREATMENT.

Dr. Caton has added an important chapter to the subject of *preventive medicine* by showing how we may prevent many cases of incipient rheumatic endocarditis from passing into permanent valvular disease by prolonged rest in bed, the administration of sodium iodide and the application of blisters.

Dr. Arthur Goulston, by his ingenious use of *cane sugar*, has given us a valuable aid in dealing with chronic heart failure. It is noteworthy that beet sugar is without effect and that the cane sugar must not be cooked.

The intravenous use of *strophanthin* in urgent cases has been found of unmistakable value. *Theocin sodium acetate* has proved its usefulness in dropsy which has not yielded to other diuretics. Sir Lauder Brunton's insistence on the importance of *morphine* in the distressing *dyspnoea* of late heart disease has promoted its general use in that condition, and the discovery of the immediate value of its hypodermic injection in *acute pulmonary oedema* (which occasionally occurs in cardiac patients) has put a valuable weapon in our hands. In "soldier's heart" *graded exercise* has expedited the generally slow recovery.

Strychnine has been unduly discredited. Surgical shock, in which it has been rightly replaced by *pituitrin*, is a different condition from ordinary heart failure, and although there are those who prefer injections of *camphor* in cardiac breakdown, we shall do wisely if we hesitate to discard from our therapeutics a remedy which the sober judgement of competent clinicians has so long relied on.

The use of *salvarsan* in cardiac syphilis appears to have special risks and, if used at all, it should probably be given in smaller doses than ordinary.

In streptococcal endocarditis (the most frequent variety) we have learnt that whereas *anti-streptococcal serum* occasionally succeeds, streptococcal vaccines almost invariably fail. *Standardized digitalis* is a valuable advance.

Three surgical procedures require medical notice. Brauer's operation of "*cardiolysis*" is of service where a heart is gravely hampered by adhesions of the pericardium to the chest wall. *Direct massage of the heart* through the diaphragm, in cases of heart failure under operation, has been the means of restoring life. *Incision of the pericardium* seems at last to be recognized as a safer proceeding than the older paracentesis.

PROGNOSIS.

The prognosis of *cardiac syphilis* has received a good deal of attention, and would seem to be very unfavourable. Dr. Mitchell Bruce has stated that only 50 per cent. of the cases improve at all, and that 20 per cent. die within a few years. Patients with syphilitic aortic disease, he finds, generally die within a little over five years. Adler and Weber, however, believe that early treatment may cure. All authorities insist on prompt and vigorous measures.

Perhaps now that fuller means of diagnosis are at our disposal, as in the Wassermann reaction, earlier recognition may lead to a better outlook.

In 1898 a distinguished authority, whose experience was chiefly derived from a great industrial area, wrote that cases of *aortic regurgitation* had never, in his recollection, survived for fifteen years. This was so different from Devonshire experience, and from experience in other non-industrial centres, that the discrepancy suggested that possibly great local differences in general expectation of life might be showing themselves incidentally in cardiac patients. Accordingly, in 1909, I examined the proportion of the population which survived to 75 and over in all the registration districts of England. The result was remarkable. In Leeds, where the shorter survivals alluded to were observed, only 6 per cent. of the population reached those ages, in Manchester only 2 per cent., whereas in some Devonshire districts, such as Axminster and Crediton, 25 per cent. did so. Since then a number of observers have repeated the older observation of cases of aortic regurgitation surviving for twenty-five and even thirty years: and a case of combined aortic and mitral regurgitation, which survived for over thirty years, had been for nearly twenty-eight years under my own observation in Exeter. This fact of *local prognosis* is one which, I would suggest, needs farther attention.

DIAGNOSIS.

A number of new instruments have been added to our equipment. The *sphygmomanometer*, introduced a little before 1900, has only come into general use since that time, and Dr. Batty Shaw has pointed out its value in distinguishing secondary from primary cardiac disturbance.

The *x rays*, with or without *orthodiagraphy*, are necessarily becoming more and more a help in the examination of our cases. Especially useful have they been in establishing or correcting the diagnosis of aortic aneurysm. As I shall presently point out, they afford valuable assistance in verifying the findings of digital percussion.

MacKenzie's *polygraph* has been an important means of distinguishing—and of giving us other means to distinguish—the different varieties of pulse irregularity. To this I shall return.

Einthoven's *electrocardiograph* promises to assist in the unravelment of certain problems. As yet, however, it is difficult to see that it has proved of much practical use to the clinician.

Leyton's *differential stethoscope* may enable us to compare clinically the relative intensity of a patient's heart sounds at different periods and under different conditions.

Even the older modes of auscultation admit of revision and comparison. Thus I have recently compared the old-fashioned "single" straight wooden stethoscope with its more popular successor, the ordinary "double" or binaural flexible stethoscope, and both of them with the almost discarded method of "immediate auscultation"—that is, of listening with the ear laid directly on the chest wall with only some thin fabric intervening. I have found that whereas a slight mitral regurgitant murmur is more loudly and distinctly heard with the double stethoscope than with the single, a slight aortic regurgitant murmur which may be missed with the double stethoscope can be heard clearly with the single; also that an aortic regurgitant murmur may be occasionally inaudible to both these stethoscopes and yet be made out unmistakably by immediate auscultation. This applies to both the upright and recumbent postures.

Sir William Osler's spots in malignant endocarditis were, I believe, discovered within the period we are discussing.

The *oculo-cardiac reflex*—which, by the way, may be lost in locomotor ataxy—may furnish us with a means of checking a heart rate just too rapid for exact examination.

In the absence of mitral stenosis or of recent vigorous exertion it appears to me that the presence of a *distantly heard first heart sound*—by which I mean "heard without a stethoscope at a distance greater than the length of the ordinary straight wooden stethoscope, that is, about 7 in."—is strongly suggestive of hyperthyroidism.

I think there can be no doubt that whilst the importance of symptoms has been rightly insisted on for many years and directions have long been given for examining hearts

after some brief exertion, the routine care, now in general use, of inquiring into evidence of cardiac failure from the degree of exertion needed to produce distress, as also the present routine of re-examining hearts after exertion, is mainly owing to the insistent teaching of Mackenzie and his school.

PHYSICAL SIGNS.

I. On Pulse Abnormalities.

We are chiefly indebted to Sir James Mackenzie and Dr. T. Lewis for the brilliant investigation of pulse abnormalities by graphic methods. The subject is most interesting and has engaged many able workers for several years past. If one cannot admit all the clinical claims which enthusiasts have made for their scientific results, it is not that one does not recognize the general debt we owe to their skill and labour.

Total Arrhythmia.—Dr. Lewis has made the interesting discovery that this well-known accompaniment of cardiac failure is caused by fibrillation of the auricle, a condition in which the auricular fibres contract in such separate and inco-ordinate fashion that the auricle as a whole stands still. As a scientific explanation of the auricular inaction and the coincident total arrhythmia of the ventricle, this is an important piece of work. But clinically it has, so far, had very little effect. As regards diagnosis, the condition underlying it has still to be determined by other and older methods; in prognosis, a condition which may end in a few weeks, or may last for years with little apparent detriment, cannot be regarded as very helpful; whilst in treatment it is difficult to see how its recognition has affected us at all.

Heart-block.—Perhaps no chapter in cardiology is more fascinating than that which, beginning with Gaskell's researches, has included such fine work as has been done by Kent and His, Tawara, Erlanger, Keith, Mackenzie, and Lewis—to mention only a few. In the future we may hope for clinical results, such as will aid us in the prognosis and treatment of the condition evidenced by the Stokes-Adams syndrome, but at present we stand as we did.

Intermissions.—Except that the premature dwarf contractions, which our stethoscopes alone formerly detected, are now called "extra-systoles," we have made no practical progress in our knowledge of these. But it is a gain to have recognized that intermissions may be due to pauses of the whole heart or to occasional heart-block.

Paroxysmal Tachycardia.—We have learnt that one variety, due to "auricular flutter," is amenable to large doses of digitalis, which convert the flutter into auricular fibrillation, which in turn, on discontinuance of the drug, reverts to the normal rhythm. In other varieties we seem to be much where we were.

Pulsus Alternans.—This sign, originally described by Traube, has lately been assigned a most serious significance. Yet so able an observer as Sir William Broadbent wrote in 1897, "I have learnt not to attach serious importance to the regular alternation of a strong and weak beat, so long as there is no great frequency with it." Carver has lately recorded its occurrence in persons with no apparent cardiac lesion, and stated that it may disappear, leaving the patient apparently none the worse. Which view of its significance is correct?

Sinus Arrhythmia.—Here we are clearly indebted to the graphic methods. They have made precise the meaning and diagnosis of this usually harmless form of irregularity. Sinus arrhythmia is a vagal irregularity, its rhythm starting, as it normally should do, from the sino-auricular node and involving the whole heart. Its pulse rate rarely exceeds 100, and more usually is as low as 60 or 50, whilst anything which quickens the pulse, such as exertion or rise of temperature, removes the arrhythmia. Atropine (which has no effect on auricular fibrillation), by its action on the vagus, removes it. With the three exceptions mentioned below it needs no treatment, not even change of habits. It is the common irregularity of childhood up to 10, a period in which premature contractions are unusual, heart-block rare, and auricular fibrillation very rare. It is less common in adults. When, as is the rule, there is an obvious relation to respiration, ordinary or deep, says Dr. Lewis, its nature is evident; a gradual waxing and waning of rate is always highly suggestive, if not conclusive. The radial beats and apex beats correspond; the heart sounds show no trace of extra-systoles. The pulse beats are full and equal in amplitude.

There are, however, three varieties in which there is no association between the pulse irregularity and phases of respiration—namely: (1) Sudden prolonged pause of the heart beat, usually with syncope—a rare condition. (2) Relatively abrupt slowing of the whole heart to 20 or 40 beats a minute with fall of blood pressure, which Lewis believes is the commonest cause of fainting attacks in adults. (3) Variation of pulse rate in phases lasting ten, fifteen, or more seconds—uncommon, sometimes following large doses of digitalis or its congeners, sometimes apart from these. All these are due to vagal influence and are removed by atropine—a valuable therapeutic indication.

It is noteworthy that Dr. Watson-Williams has observed that well marked respiratory undulations in a boy's pulse "implied, if anything, that he would make a good sportsman."

II. Influence of Respiration on Murmurs.

It has long been taught that systolic heart murmurs which are obliterated by a deeply-held breath should be suspected of being exocardial (so-called "respiratory murmurs"), that is, negligible so far as the heart is concerned. I have, however, recently found that a deep-held inspiration is capable sometimes of obliterating the soft diastolic murmur of slight aortic regurgitation in young adults. The chief significance of this lies in the doubt it casts on the present interpretation of systolic "respiratory" murmurs.

III. The Influence of Posture.

The advice to examine heart patients both erect and recumbent is old, yet it was rarely followed until recently. "Scientific" accounts of cases, twenty years ago, were constantly being published with no note of the posture at the time of observation. No ordinary textbook that I know of prior to 1906 (when I published what I believe were the first observations on the effect of posture on the normal cardiac sounds and on the normal cardiac dullness), and few since, have said a word about posture in percussion—Broadbent's book does not once allude to it! Only Dr. Blackhall-Morison, in his work on *Heart Failure* (1897), gave a figure illustrating the change in the dullness in a case of mitral disease (the first such figure, I believe, ever published), and added this admirable statement: "Whatever method be pursued in determining the dimensions of the heart by percussion, it is of the first importance that the posture of the patient should, so far as possible, be exactly the same on successive occasions when this point is under observation."

For the following additional points I have made myself responsible:

1. That the real width of the heart is most closely determinable by percussion when the patient is erect.
2. That in cases of enlarged heart the difference in the dullness produced by change of posture from the recumbent to the erect may be relatively great; three examples will suffice:

		Erect.	Recumbent.
Case A.	...	9 in.	5 in.
Case B.	...	8½ in.	4½ in.
Case C.	...	8 in.	5 in.

These show what confusion may arise from examining the patient in different positions on different occasions.

3. That this difference is chiefly due to the change in the rightward edge of dullness.

These three facts have recently been made abundantly evident by x-ray photographs, in which the lateral limits of dullness, previously percussed out in the two positions, have been marked by pieces of metal attached to the chest wall.

4. That the presystolic murmur of mitral stenosis is, sometimes only audible in the erect position.

5. That the systolic murmur of aortic stenosis is sometimes only audible in the recumbent position.

6. That an accentuated and reduplicated second sound over the pulmonary artery is best heard in recumbency and that sometimes the reduplication is only evident in recumbency.

7. That the cavity of the chest is usually appreciably deeper antero-posteriorly in the upright than in the recumbent position. Dr. Blackhall-Morison's luminous remark, that a much-enlarged heart has to be considered as a form of intrathoracic tumour, lends importance to

this fact. Also, from a consideration of the differing influence of posture on the best-known heart murmurs together with this effect on chest depth, it has been possible for the first time (1902) to supply a rational explanation of the influence of posture on heart murmurs—namely, that it is due, in part to the effect of gravity on the intracardiac currents, and in part to the change in the chest depth. It is necessary to recall this explanation, as it has recently been misquoted.

8. That what I have called *distantly-heard heart sounds* are more distantly heard in recumbency. Thus in a case of Graves's disease, the first sound was audible 5 ft. away in the recumbent position, but only about 2 ft. away in the erect.

9. That from all the above considerations it is clear that no important cardiac case is properly examined or described in which posture is left out of account.

10. That in certain cases of *cancer*, especially cancer of the digestive organs and in their later stages, the recumbent cardiac dullness (R. C. D.) is remarkably diminished (to under 2 in., or more typically to about 1 in.), or even altogether lost. This "*cardiac sign in cancer*" I have found of great value in the diagnosis of obscure cases. In one series of fifty cases there was only 6 per cent. of error.

Another, and a very interesting effect of change of posture, is that described by Dr. Blackhall-Morison, which he considers valuable as a warning of grave heart failure. It is that the crepitations of pulmonary congestion, if heard at one lung base, can be transferred at once to the base of the other lung by turning the patient on to the opposite side from that on which they were first audible.

Dr. Batty-Shaw has used change of posture to distinguish the *pulmono-arterial diastolic murmur*, due to high pulmonary pressure. In the erect posture this murmur, being heard alone, might be taken for the murmur of aortic regurgitation. "Recumbency will, however, change the whole picture and reveal the presence of an obstructive or of a double mitral murmur."

ETIOLOGY.

The most important etiological study has been that of the so-called "*soldier's heart*"—the "*irritable heart*" of Da Costa in the American Civil War—for which the late war has furnished a superabundant mass of material. In its most striking form the signs of structural heart disease are absent, but the patient is short of breath on exertion, easily exhausted, and complains of palpitation, precordial pain, giddiness, and more rarely of actual fainting; exertion, excitement, and sometimes change of posture, unduly hurry his pulse, and this hurried pulse is unduly long in returning to its normal.

In other cases there may be slight cardiac enlargement, with soft systolic murmurs, sometimes perhaps due to relative incompetence, or being sometimes "haemic" or "respiratory" in character. Now and then the syndrome may be superposed on actual structural heart disease.

At first the condition was attributed to physical overstrain, and especially the overstrain of men unaccustomed to strenuous exertion suddenly submitted to arduous military training, aggravated perhaps by excessive cigarette smoking. But as the war went on it was noticed to follow on various infective diseases, on mental shock, and on exposure to great heat of climate. Cardiac drugs were found useless, and rest was then thought to be the only remedy. The cases were, as Da Costa had recorded, exceedingly obstinate. Presently the disease appeared amongst the women undergoing anxiety at home, and its psychological aspects came more clearly into view.

Present-day opinion may perhaps be briefly thus stated. It is a condition of neurasthenia in which the heart is especially affected, depending in part on inherited physical and psychical defects, and more immediately on infective toxæmia (as from enteric, malaria, trench fever, amoebic dysentery, tuberculosis, influenza), or on exposure to high temperatures, the cumulative strain of fatigue with insufficient food and sleep, or great nervous shock or stress, associated sometimes with endocrine disturbance (thyroid or adrenal), the psychical factor becoming evidently more and more important as observations accumulate. Rest, though useful, indeed necessary, at first, has later been superseded, after a sufficient interval, by carefully graduated exercises, carried on amidst the curative

psychical atmosphere of a busy and successful treatment centre. For such "ragal" symptoms as fainting, with slow, feeble pulse, atropine has been used with advantage. But the disease remains exceedingly refractory. Many cases are still uncured, and many have only recovered after many months. The majority may, however, be perhaps regarded as recovered.

Speaking with much diffidence from a limited personal experience I cannot but think there are possibly several types still not disentangled. For I have seen cases which seemed obviously associated with hyperthyroidism, and others equally suggestive of toxæmia with no obvious endocrine change—one such I afterwards heard was fatal from syncope.

For the rest, still uncured, we may well continue to hope; but Da Costa's experience that 23 out of 200 afterwards developed "cardiac hypertrophy," and the record of some writers on the Balkan war cases (quoted by Dr. Carey Coombs) that "premature arterio-sclerosis" (probably the same condition as Da Costa's) commonly occurred as a sequel, must be borne in mind. It will be important to determine, if we can, what particular causes have been connected with the cases in which such a sequel shows itself.

In conclusion, gentlemen, I hope that the shortcomings, which you cannot but find in this very condensed summary, will meet with the excuse that my material has been exceptionally difficult to deal with. If in anything I have seemed too frank, I hope I have at least not failed to be fair.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

RADICAL CURE OF FEMORAL HERNIA BY THE INGUINAL ROUTE.

LIKE the majority of surgeons, I have for many years operated upon femoral hernia by the ordinary methods through the saphenous opening. Two or three years ago my attention was called to the method of operating by the inguinal route, and I have no hesitation in strongly recommending it. Mr. Percival Cole's description of the operation in the *BRITISH MEDICAL JOURNAL* of June 21st, 1919, is an excellent one and should be followed.

The advantages of this method are: (1) The greater likelihood of a permanent cure, for the ordinary operation, even in the hands of experts, is attended by frequent recurrence, and I have at present under my care a woman with a femoral hernia upon whom six unsuccessful operations have been performed by hospital surgeons. (2) A thorough examination of the gut can be carried out, and, if necessary, the gut can be resected. Quite recently I drew down and repaired the places which had been damaged in a tightly strangulated hernia. By the old method this could only have been done by weakening the ring, with the probability of a speedy return of the hernia. (3) Abnormal vessels are avoided. This may not be of much importance, but quite recently I tied the obturator as it curved round the neck of the sac.

There are also disadvantages. It is a rather more difficult operation than the ordinary one, and I have found the passage of the needle when suturing Cooper's ligament to the conjoined tendon troublesome, especially in stout patients. It is easier in females than in males, as in the latter the cord obstructs. In a recent textbook the operation is not, in my opinion, correctly described, for whereas the conjoined tendon should be sutured to the posterior border of the ring, the book in question describes the suture of the ring itself and does not mention the conjoined tendon.

Liverpool.

G. P. NEWBOLT, C.B.E., F.R.C.S. Eng.

ECTOPIA VESICAE SUCCESSFULLY TREATED BY TRANSPLANTATION OF THE TRIGONE INTO THE SIGMOID.

MANY operations have been devised to remedy this distressing condition, but few have proved satisfactory. None of the many attempts to restore the bladder by plastic operations has answered the purpose; it is impossible to reconstruct the sphincter, and the operations have added

little, if anything, to the comfort of the patient. Attempts to transplant the ureters into the sigmoid or rectum have sometimes succeeded, but the great objection to all operations of this kind is the very serious risk of infection spreading along the ureter to the pelvis of the kidney.

It is essential that the valvular action of the ureteral orifices should be preserved, and this can apparently be secured by the operation described by Maydl in 1896, in which the trigone of the bladder is transplanted into the sigmoid flexure of the rectum. Such an operation was recently performed by myself, and the result up to the present time has been completely satisfactory.

A girl, aged 6, was admitted to the East Suffolk Hospital in May, 1920; the operation was performed on June 2nd. The upper three-quarters of the bladder was completely removed by a semicircular incision through the skin just outside the junction with the vesical mucous membrane, extending into the peritoneal cavity; the incision was carried across the base just above the trigone, and the abdominal cavity plugged with a gauze pad.

The base of the bladder, an elliptical area of $1\frac{1}{2}$ in. across by $\frac{3}{4}$ in. vertically, including the trigone and the ureteral orifices—situated $\frac{3}{4}$ in. from each end of the transverse diameter—was then raised by dissection, care being taken to avoid stripping the ureters and interfering in any way with their vascular and nervous supply. A loop of the sigmoid could easily be brought down to the level of the raised trigone. The loop being clamped, a longitudinal incision was made along it through the sero-muscular coat, and the posterior surface of the upper margin of the portion of bladder was sewn to the bowel about $\frac{1}{2}$ in. from this line by a continuous Lembert suture of fine silk. The bowel was then opened and the mucous membrane of the bladder and bowel were sewn together by a continuous catgut suture passing through the whole wall of each viscus, exactly as in the ordinary operation for gastro-jejunostomy. The silk suture was then continued for the remainder of the circumference through the sero-muscular coat of the bowel and muscular wall of the bladder, in the same way as the operation of gastro-jejunostomy is completed, so that the bladder wall formed part of the wall of the sigmoid, completely closing the gap. The bowel was replaced and the gap in the abdominal wall resulting from the removal of the bladder closed by silk-worm sutures. The patient made an excellent recovery; there was no shock and the convalescence was normal.

At the present time—more than five months after the operation—the patient is perfectly well and happy, with a soundly healed scar. The bowel has retained the urine without the slightest difficulty; there has been no leakage or incontinence. The urine is retained all night, from 9 p.m. to 7 a.m., and during the day is passed at intervals of four or five hours.

HERBERT H. BROWN, O.B.E., M.D., F.R.C.S.,

Ipswich. Surgeon to the East Suffolk Hospital.

Reports of Societies.

"DOUBLE UTERUS."

At a meeting of the Edinburgh Obstetrical Society, held on December 8th, 1920, with Dr. WILLIAM FORDYCE, President, in the chair, Dr. D. ROBERTSON DOBIE read a paper on pregnancy and labour in a double uterus. He discussed the different ways in which this condition may impede labour, and described an illustrative case. On examination after the onset of labour the vagina was found to be blocked by what seemed a pedunculated mass. At a later examination only did the actual condition become clear. By this time the foetal head had come down, but it was held by a band, like a strong adhesion, crossing the vagina. This was the septum between the two cervixes, and had to be divided before delivery was possible. The extraction was then accomplished with forceps. After delivery the pedunculated mass that blocked the canal in the early stages was found to be the unimpregnated uterus, the cervix of which had been driven down to the vulvar outlet.

Dr. HAULTAIN referred to the great difficulty in diagnosis presented by these cases. He mentioned a case where the unimpregnated half of the uterus had been mistaken for a fibroid and had been removed. Dr. BALLANTYNE pointed out that the expression "double uterus" was a misnomer, as the condition was really one of two half uteri.

Dr. HAIG FERGUSON referred to a case in which the patient aborted from one half of the uterus at three months and six months later was delivered of a full-time child from the other half. Dr. LACKIE recorded a case where a thick band, similar to that in Dr. Dobie's case, blocked the

canal. In another case the patient menstruated from one side one month and from the other side the following month.

Dr. H. R. A. PHILP then gave a communication on obstetric practice amongst the Akikuyu tribe of Kenya Colony, British East Africa.

He described the ceremonies which are carried out at the initiation of the girls into the tribal life. The most barbarous of these consists in the removal of the external genital organs. The girls are lined up in a sitting posture with the legs separated, whilst an old woman passes from one to the other and, regardless of their cries, removes the labia with a sweep of her knife. This is an invariable practice in the tribe, although the missionaries are making every effort to stamp it out. Another barbarous custom is the sending of difficult labour cases into the bush to die.

Revielus.

ORTHOPAEDIC AND REPARATIVE SURGERY.

MORE than fifty surgeons have combined to make public the fruits of their experience of modern orthopaedic and conservative surgery in the two volumes of *Chirurgie Réparatrice et Orthopédique*, published under the direction of Messrs. JEANBRAU, NOVÉ-JOSSERAND, OMBREDANNE, and DESROSSES, so that this work may be almost considered as a system of reparative surgery. The preface, in which it is truly said that the advance in the treatment of injuries, which took place during the war, must be maintained for the benefit of the injured in peace time, is for the rest a paean of triumph of French surgery; for it all advances made during the war are claimed; no credit, so far as we can find, is given to allied or enemy surgery. But this is a harmless exhibition of national vanity which may be pardoned in the circumstances and which does not seriously detract from the value of the book as a guide to treatment, seeing that the various authors, while sufficiently patriotic, do not hesitate to quote the names of alien surgeons.

It is difficult within the scope of a review to criticize a work of this magnitude adequately, but an attempt to indicate its merits is possible. It deals with the treatment of wounds and injuries of every description in war and peace, in an introduction and sixteen chapters. In addition, it contains an article of 47 pages by Professor Jeanbrau on French war pensions, and the text of the law of March 31st, 1919, on this subject is printed as an appendix. A bill has been introduced in the Senate to extend the provisions of this law to the civil population and to provide the necessary special clinics.

In the introduction Dr. Lemaitre discusses the general principles of the modern treatment of wounds, laying more stress upon the removal of injured tissue and even on excision than on irrigation methods, such as that of Carrel, in the treatment of infected wounds. Professor Patel deals with the operative and orthopaedic treatment of war fractures and the application of these methods to civil practice. In this connexion it is as well to note that in France "orthopaedic" is used as contrasted with "operative" to denote treatment by the use of instruments alone, a sense which is happily obsolete in this country and in America.

Dr. Ledoux-Lebard defines the general principles of the radiological localization of foreign bodies and the proceedings necessary for their extraction. The chapters by Professor Ombredanne on the late removal of projectiles, and particularly those chapters concerned with plastic surgery, on which he is an acknowledged authority, are very valuable. The several chapters on orthopaedic and prosthetic apparatus are welcome, for these are subjects not adequately dealt with in surgical works in the English language. In these chapters Ducroquet, Calvé, A. Tières, Nové-Josserand, Hendrix, and others describe not only suitable apparatus, but the principles upon which they should be constructed.

Dr. Roux-Berger contributes an interesting and lucid article on the sequelae of wounds of the chest and their treatment by the methods which constitute one of the

¹ *Chirurgie Réparatrice et Orthopédique*. Publié sous la direction de MM. E. Jeanbrau, P. Nové-Josserand, L. Ombredanne, et P. Desroses. Secrétaire de la rédaction. Paris: Masson et Cie. 1920. 2 vols. (Roy. 8vo. pp. 671; 518 figures, 7 plates. 80 francs net.)

striking advances made by surgery during the war. The boldness of conception and skill in execution of this branch of surgery is well brought out by the descriptions and excellent illustrations in this chapter. Sicard and Froelich write on the post-traumatic sequelae of injuries of the spine and of the contents of the spinal canal, and the latter has some useful pages on the so-called spontaneous lesions of the vertebral column which should be distinguished from the results of traumatism.

The abdomen, which offers so wide a field for surgery in primary lesions, does not bulk largely in reparative surgery. Ventral hernia and artificial anus and their cure, and urethral fistula are the only subjects in this chapter, and the last seems to be hardly correctly described as an abdominal lesion.

Osteo-articular lesions necessarily occupy much space. The treatment of ankylosis, of malunion of fractures, of pseudarthrosis in all its forms and of flail joints receive full notice from a number of authors.

Professor Lambret's article on cinematization of amputation stumps is short, but to the point, and we agree with his conclusions. The suggestions of Vanghetti have been put in practice for at least five years, but we are not yet in a position to estimate their practical value. This, as Professor Lambret says, is largely due to the want of satisfactory prostheses for these cases. The technique of the operations for the provision of plastic motors has been worked out and may be considered established: it is comparatively easy thus to procure adequate and resistant sources of power, but until satisfactory prostheses are available we are compelled to suspend judgement on this subject.

The production of this work, with its wealth of excellent illustrations, redounds to the credit of the publishers and editors who have been so enterprising as to undertake it and carry it through to so satisfactory a result. We have only one complaint to make, and when we call attention to the fact that an alphabetical index is lacking, we do so in the hope that this serious defect will be remedied in the next edition.

ENLARGEMENT OF THE PROSTATE.

To grow old gracefully is the hope of most men, but to grow old healthfully is the expectation of few. It is a source of immense satisfaction that surgery can do so much to make the old age of many men happy. When one reads in the new edition of FREYER'S *Clinical Lectures on Enlargement of the Prostate*² the grateful letters and comments of many of the patients to whom prostatectomy has given a new lease of life one feels that much good, after all, is being done, and the unpalatable memories of failures are forgotten. The operation of suprapubic prostatectomy associated with Sir Peter Freyer's name may now be regarded as standardized, to use a commercialism. Certainly in this country no other operation has anything like the same vogue, and the only comments in the past few years have been in the direction of prevention of such complications as haemorrhage and post-operative obstruction, and the advisability of doing a two-stage operation. There is no need to call attention to particular points in these lectures. Suffice it to say that they are written in racy, vigorous style, the details of cases cited are invariably interesting, and the work is founded on 1,600 cases carefully noted and honestly followed out to their conclusion. The book is one which certainly every surgeon ought to know and one which every general practitioner will find helpful.

This edition contains a new chapter on cancer of the prostate, a condition which is apparently more common than was formerly supposed. In Freyer's experience 13.8 per cent. of all his cases were clinically malignant, all but two cancer. He acknowledges that microscopic examination was not made in every case operated on, so that possibly the percentage is higher; indeed, it is so suggested by Albarran and Hallé, who argue that "adenomatous transformation of the prostate in advanced age is in a number of instances the primary stage of a malignant degeneration." We have known of other surgeons who have been surprised to find that a small tough prostate

difficult to remove, but regarded as simple pathologically, proved on examination to be cancerous. It would be well worth while submitting every prostate removed by operation to microscopic examination. The diagnosis of cancer of the prostate is by no means certain. If in a patient presenting the usual symptoms of prostatic enlargement one learns that "the symptoms have run their course rapidly in a few months only instead of as many years"; if the rectal examination discovers the prostate to be hard, irregular, immobile, tender to touch; and if catheterization is painful and the instrument meets with sudden resistance in the prostatic urethra, then the conclusion that the prostate is cancerous may safely be drawn. As to operability, experience shows that in some few cases enucleation is practicable and apparently curative, but the surgeon will require to determine the matter for himself with one finger in the rectum and the other in the bladder through the suprapubic wound.

The chapter is a welcome addition to the book, though, being cast in the form of a clinical lecture, admittedly it touches not much more than the fringe of the subject. It is not unreasonable to hope that doctors will make rectal examinations more frequently, and so capture these early cancerous prostates and give both patient and surgeon a chance.

ANATOMY AND MUSCULAR EXERCISES.

THAT a second edition of *Applied Anatomy and Kinesiology*³ should have been called for within two years of the appearance of the first is evidence of a demand for anatomical knowledge on the part of those who teach the various systems of physical exercises now practised, and also on the part of their pupils. We agree that our knowledge of muscles, particularly of their combination to produce familiar actions, is not well set out in our standard textbooks of anatomy, and that there is great need for a book such as this in which movements of the living body form the theme and the dissected body the dissertation.

In spite of very excellent illustrations and clearly worded explanations, Professor BOWEN's second edition suffers from the defects of the first: it is based on a superficial knowledge of the physiology of the human body, which, in our opinion, is even more important to an instructor in gymnastics or graduated exercises than a complete mastery of the anatomical details relating to muscles, bones, and joints. To exemplify the reason for making this criticism the reader may be referred to the chapter devoted to the upright posture. There the student is taught that in some respects the human body is not adapted for the upright posture—as shown by the lack of valves in the inferior vena cava and the presence of valves in intercostal veins where they are regarded as unnecessary. The inferior vena cava is part of the great venous cistern from which the heart is filled; even moderate exercise leads to the distension of this cistern; violent and prolonged exercise has been known to cause it to rupture. If valves were provided they would be not only useless, but injurious. The valves in the intercostal veins, as in veins arising in and passing among muscles have nothing to do with the upright or horizontal posture, but are provided to secure the passage of blood towards the heart during intermittent and alternating action of the adjacent muscles. No one can teach or practise exercises intelligently unless the significance of venous valves has first been grasped.

The "location of the vermiform appendix" is also cited as another instance of imperfect adaptation to upright posture in man. "The upright position shifts this structure from the highest level of the digestive tract in the quadruped to the lowest in man, where it is subject to much greater pressure and liable to irritation by fragments of food forced into it by changes in pressure." Such a statement will find no support from what is known of the comparative anatomy or of the physiology of the intestinal tract.

We might have cited statements equally ill-founded from the chapters devoted to the spinal musculature, to the action of the muscles of the leg and foot in maintaining the weight of the body in standing and in walking, or in

²Clinical Lecture on Enlargement of the Prostate. With a description of the organ. By Sir Peter Freyer. D. London: Baillière, Tindall, and Co. 1917. 56 plates. 10s. 6d. net.)

³*Applied Anatomy and Kinesiology: The Mechanism of Muscular Movement.* By Wilbur Pardon Bowen, M.S., Professor of Physical Education, Michigan State Normal College. Second edition. Philadelphia and New York: Lea and Febiger. 1919. (Med. 8vo. pp. 332: 197 figures.)

the chapter devoted to breathing and breathing exercises. The book in many respects is so good that we hope in a future edition the principles of physiology which underlie the practice of "kinesiology" may receive a rendering more in keeping with modern knowledge.

DISEASES OF AVIATORS.

AVIATION demands a high degree of physical fitness and mental balance from those devoting themselves to it, whether in war or peace. Drs. MAUBLANC and RATIÉ, with several years of experience behind them, have written a short and lucid account of the methods they employ in the medical examination of aviators and candidates wishing to take up aviation; they lay stress on the importance of the following points in any such examination. Candidates should be rejected if their past history gives evidence of major or minor epilepsy, tuberculosis, recent malarial infection, or war wounds leaving behind them definite evidences of injuries to nerves, joints, the central nervous system, or the lungs. Similarly, valvular disease of the heart, high arterial blood pressure, or marked functional cardiac disturbances, emphysema, or tuberculosis of the lungs, the presence of extensive pleural adhesions, definite diseases of the abdominal viscera generally, diminution of the visual fields or marked ametropia, deafness, liability to attacks of vertigo, and inadequate response to tests of sensorial acuity or variations of equilibrium, are all adequate causes for the rejection of any candidate. The authors devote forty pages to the description of their various methods of testing the reactivity to sensory impressions (visual, auditory, tactile) and to changes of equilibrium; these methods are applied to candidates who have passed the more medical examination indicated above. The book is clearly written, and should be in the hands of all medical men who have to do with aviators or the selection of candidates for aviation.

The book, *Aviation Disease, its Cause and Remedies*,⁵ by Professor CRUCHET and Dr. MOULINIER, deals with a subject studied by these authors since the year 1910. The symptoms of the disease come on chiefly at the higher altitudes of flight and in the course of long flights; they are aggravated by unduly rapid descents. They consist of such things as dyspnoea, palpitations, nausea, deafness, psychical defects of vision, loss of the sense of orientation, headache, lumbago, and increasing slowness of ideation, or somnolence. Naturally, the clinical picture varies in different instances. Discussing the causes of aviation disease, the authors lay great stress on the rise of minimum arterial blood pressure that always is observed in it, but is not observed in the well-trained and fit aviator; other factors, such as fatigue, exposure to cold, intellectual and emotional exhaustion, temporary or permanent disorders of the auditory apparatus, and undue rapidity in descending to earth, are contributory but less important in the development of the disease. In effect, the whole syndrome is brought about by unduly rapid rising to high altitudes, as in mountain sickness, or unduly rapid descent. Discussing the training of aviators with a view to rendering them less liable to the physical and cardiac fatigue that lead to the development of the symptoms described above, the authors emphasize the importance of giving rest to aviators as soon as they develop evidences of such fatigue, whether mental or bodily; it may be added that a good picture of the mental exhaustion typically demanding a change of occupation in an aviator is furnished in some chapters of Mr. J. E. Gurdon's *Over and Above*,⁶ a book describing the experiences of an aviator flying in France during the recent war. Professor Cruchet and Dr. Moulinier produce a considerable amount of evidence in favour of the views they advance, and their little book will be read with interest by aviators and the medical men who have charge of them.

⁵ *Guide pratique pour l'Examen Médical des Aviateurs des Candidats à l'Aviation et de Pilotes.* Par Drs. Maublanc et Ratié. Médecins du Centre d'Aviation de Chartres. Paris: J. B. Baillière et Fils. 1920. (Imp. 15mo, pp. 109; 25 figures. Fr. 3.)

⁶ *Le Mal des Aviateurs: Ses Causes et ses Remèdes.* Par Dr. René Cruchet, Professeur agrégé à la Faculté de Médecine, et Dr. René Moulinier, Médecin de la Marine. Paris: J. B. Baillière et Fils. 1920. (Post 8vo, pp. 94; 12 figures. Fr. 3.)

⁷ *Short Practice of Midwifery.* By Henry Jellett, M.D., F.R.C.P. 1920. (Cr. 8vo, pp. 311; 69 figures. 7s. 6d. net.)

MIDWIFERY.

Dr. JELLETT'S *Short Practice of Midwifery*⁷ is so well known that the appearance of an eighth edition calls for little more than mention. The text has been thoroughly revised and, where necessary, brought into line with the practice taught and carried out at the Rotunda Hospital, Dublin, during the author's term as Master. Many of the illustrations have been redrawn and improved, and Dr. English has added a most interesting statistical table in the form of an appendix, which shows the nature and proportion of all the cases treated in the Rotunda during the masterships of Sir W. J. Smyly, Dr. R. D. Purefoy, Dr. E. H. Tweedy, and Dr. Jellett. As the grand total of cases so reviewed is over fifty-one thousand, it will be realized that few similar tables are available from which more reliable data can be drawn. To teachers this appendix will prove of the greatest value and interest. From every point of view this remains one of the best of the smaller textbooks of midwifery in the language.

An equally well known book in its sphere is Professor JARDINE'S *Practical Textbook of Midwifery for Nurses*,⁸ which now makes its appearance in a seventh edition. In substance it remains much as it was in the last edition, and the teaching contained in it has proved so suitable to the needs of so many nurses that not much change could be either expected or desired. The new edition will continue to be the *vade mecum* of many maternity nurses, and they will find in its pages practically all that they require to know either for the practice of their profession or for the examinations of the Central Midwives Boards.

A SYNOPSIS OF MEDICINE.

Books which attempt to condense into a short "compendium" the whole survey of medicine turn out, as a rule, to be cram books for the student, and more often than not, bad cram books. Dr. TIDY, in his *Synopsis of Medicine*,⁹ has succeeded in compiling a better compendium than seemed possible to expect. In compact form this volume furnishes an admirable *index medicus*. The author, in his preface, expresses very modest hopes that his book may sometimes prove useful "to those who have to revise rapidly their knowledge of medicine in general or of some disease in particular." Its usefulness will not be so limited. The scope of the work is far wider than in the majority of similar books. To take a single example: "Tuberculosis" is discussed more fully and a good deal more intelligibly than in the average textbook. Modern experiments and modern theories are adequately presented. Or again, in the section on diseases of the nervous system, the anatomy and physiology of the nervous system will be found clearly described and ably linked up with the clinical manifestations of pathological changes. The discussion of carbohydrate metabolism in reference to diabetes is wonderfully clear and comprehensive. Throughout the book "treatment" meets with ample consideration, and this fact alone will enhance its value enormously for the busy practitioner. Dr. Tidy is to be congratulated on having written a good book and given it a good index. The publishers have so contrived, without sacrificing the quality of either the paper or the type, that it will slip into a fair-sized overcoat pocket.

NOTES ON BOOKS.

DR. GABRIEL BIDOU is known as the author of a monograph on instrumental orthopaedics, which was reviewed by us in our issue of August 2nd, 1919, p. 138. In the pamphlet he has recently issued on the action of artificial muscles¹⁰ the same subject is dealt with, and a walking instrument for a case of paralysis of the lower limb is

⁷ *Short Practice of Midwifery.* By Henry Jellett, M.D., F.R.C.P. 1920. Eighth edition, revised. London: J. and A. Churchill. 1920. (Demy 8vo, pp. 311; 69 figures. 7s. 6d. net.)

⁸ *Practical Textbook of Midwifery for Nurses.* By Robert Jardine, M.D. Seventh edition, revised and enlarged. London: Henry Kimpton. 1920. (Cr. 8vo, pp. 311; 69 figures. 7s. 6d. net.)

⁹ *Synopsis of Medicine.* By Henry Letheby Tidy, M.A., M.D., F.R.C.P. Bristol: J. Wright and Sons, Ltd. London: Marshall, Hamilton, Kent and Co. Toronto: Macmillan, Ltd. 1920. (Cr. 8vo, pp. xv+952. 15s.; postage 1s.)

¹⁰ *Des action musculaires artificielles.* Par Dr. G. Bidou. Paris: "La Vie Médicale." 1920. (Fcap. 8vo, 15 pp.; 4 figures 2 plates.)

described and illustrated. Reproductions of cinematographic films of the patient walking with and without the appliance are appended, and are of some interest. Dr. Bidon employs spiral springs, generally in groups, as artificial muscles, so adjusted in strength and in leverage as to help or replace paralysed muscles. Another use to which he puts the springs is as antagonists; their action then is that of a spring buffer which comes into play at the end of the movement.

APPLIANCES AND PREPARATIONS.

Improvements for Use with Gas-Oxygen-Ether Outfit.
MR. H. EDMUND G. BOYLE (London, W.) writes: The accompanying illustrations depict some improvements

that have been made for use with my gas-oxygen-ether outfit. The first depicts an improved ether or mixture bottle; this comprises a three-way valve, below which is a perforated cup that can be raised or lowered upon the inlet tube inside the bottle. The inlet tube is perforated in two places, the upper being inside the cup and the lower one below the cup. The open end of the tube makes a third aperture. A filling funnel is placed behind the valve. The advantages of this bottle are that the anaesthetist can graduate the amount of ether or mixture better than was possible with the older pattern, for with this bottle the gases can pass in three ways: (1) To the patient direct and without any ether; (2) over

the surface of the ether or mixture, thus giving quite a small amount; (3) through the ether or mixture when the anaesthesia has to be deepened. The second illustration depicts a nasal attachment; this comprises a metal stirrup to which are attached a couple of short soft rubber tubes. I have found this very useful for endobuccal and endopharyngeal anaesthesia, and especially for such cases as diathermy of the tongue or palate, or for oesophagostomy and bronchostomy. It is also very useful for some operations upon glands in the neck, enabling the anaesthetist to keep well out of the way of the surgeon. The rubber tubes should be about four inches long.

MEMORIAL TO SIR VICTOR HORSLEY.

A GENERAL COMMITTEE, formed some time ago to take steps to promote a memorial to the late Sir Victor Horsley, has issued the following circular letter:

It has been decided, at a meeting of friends and former colleagues of the late Colonel Sir Victor Horsley, to take steps to commemorate his services to science and the Empire by the foundation of a lectureship or scholarship bearing his name.

The tragic circumstances of his untimely death while on service in Mesopotamia are still fresh in remembrance, and though the absence of so many medical men on war service prevented an earlier movement, we are satisfied that it is not too late for the recognition in a permanent form of Sir Victor's life and work.

He was one of the most noteworthy students of University College Hospital, a very distinguished medalist and graduate of the University of London, and a leader and first Chairman of the Representative Meeting of the British Medical Association. He was a Fellow of the Royal Society and a pioneer in the research work connected with the surgery of the brain and nervous system and the causation of myxoedema; and as secretary of the Commission, appointed to inquire into the value of Pasteur's method of treating rabies, his investigations at the Brown Institute were of the utmost value as proving the possibility of stamping out rabies in Great Britain.

Many students have cause to be grateful to him for his painstaking teaching and help in their work; and in addition to his appointments as surgeon to University

College and Queen Square Hospitals he had a very large consulting practice.

No record of Sir Victor Horsley's life-work, however brief, would be complete without mention of his unselfish enthusiasm for the social betterment of his fellows. Over and above his great achievements in science and in surgery he will ever be remembered for his devotion to the causes of temperance, the enfranchisement and equal treatment of women, the education and welfare of children, and the removal of the abuses inherent in the slums of our great cities.

Vehemence in pursuit of his political ideals sometimes gave offence, but this can be forgiven and forgotten, and there remains only the memory of a unique character, whose brilliance shed its lustre on his profession and his life-work.

It is suggested that the most appropriate trustees would be the Senate of the University of London, and that if a Lectureship should be finally decided upon, the subject should be left widely open so as to secure the services of men distinguished in some department of public life who might consider it an honour to be the "Victor Horsley Lecturer" for the year.

General Committee—Sir Charles Ballance, K.C.V.G. (Chairman); Right Hon. Christopher Addison, M.P., Right Hon. Sir T. Clifford Allbutt, K.C.B., F.R.S., Donald Arnott, C.M.G., Dr. T. Ridley Bailey, Sir Hamilton Ballance, K.B.E., C.B., Sir Thos. Barlow, Bt., K.C.V.O., Dr. J. O. Walchin Barratt, Lady Barrett, C.B.E., Sir H. R. Dever, Bt., Sir John Laud-Sutton, Dr. G. F. Blacker, C.B.E., Dr. R. A. Bolam, O.B.E. (Chairman of Council, British Medical Association), C. J. Bond, C.M.G., Sir Anthony Bowly, K.C.B., K.C.M.G., K.C.V.O., Sir J. Rose Bradford, K.C.M.G., C.B., C.E., F.R.S., S. H. Burton, F.R.C.S., Dr. R. Farquhar Buzzard, Dr. W. Watson Chayne, Dr. R. N. G. C.B., Dr. R. H. Clarke, Dr. Alfred Cox, O.B.E., Professor Crile (Cleveland), Dr. Douglas, Mrs. Lawest, Sir David Ferner, F.R.S., Right Hon. Lord Edmond Fitzmaurice, Right Hon. T. R. G. £10.—Right Hon. Lord Edmond Fitzmaurice, Sir Felix Semon, K.C.V.O., Dr. Mary Sturge, Dr. Slinger, C. J. Bond, C.M.G., Dr. Farquhar Buzzard, Right Hon. Leif Jones, Percy Sargent, C.M.G., D.S.O.
£5.—Sir W. Arbuthnot Lane, Bt., Sir J. Sims Woodhead, K.B.E., N. Bishop Harman, Dr. H. H. Tooth, C.B., C.M.G., Dr. Otto Mar., Dr. G. Salusbury MacNalty, Dr. Ewen J. Maclean, Edward J. Domville, O.B.E., S. H. Burton, J. Smith Whitaker, Sir John Laud-Sutton, Dr. G. E. Blacker, C.B.E., Lieut. Colonel R. McCarrison, Mrs. McCarrison, H. Hawley, Raymond Johnson, O.B.E., Dr. Gordon Holmes, C.M.G., C.B.E., Sir Hamilton Ballance, K.B.E., C.B., Dr. W. H. Wilcox, C.B., C.M.G., Society of Members of the Royal College of Surgeons, Professor R. H. Starling, F.R.S.
£2 10.—Right Hon. Sir T. Clifford Allbutt, K.C.B., Sir Charles Ballance, K.C.M.G., Dr. A. Fulton, Sir J. Rose Bradford, K.C.M.G., C.B., C.E., Bt. Hon. T. R. Forbes, Dr. Frank Hinds, W. G. Spencer, F.R.C.S.
£1 3s.—Mr. and Mrs. Stephen Paget, Sir Rickman J. Godlee, Bt., K.C.V.O.
£2 2s.—Dr. R. A. Bolam, O.B.E., Dr. T. Ridley Bailey, Sir T. Jenner Verrall, L.L.D., Dr. Dawson Williams, Dr. R. H. Clarke, Dr. Percy Rose, Dr. Steen, Dr. Lauriston Shaw, Dr. E. W. Goodall, O.B.E., Dr. Alfred Cox, O.B.E., Dr. Riden, Lady Barrett, C.B.E., Sir A. W. Mayo-Robson, K.B.E., C.B., C.V.O., Sir Leonard Rogers, C.I.E., M.D., Sir Hugh Dever, Bt., M.D.
£1 1s.—Dr. C. L. MacLennan, Dr. Garstang, Dr. Hawthorne, Sir Charles Harrison, Dr. O'Sullivan, Dr. Henry Sturge, Colonel Mansell Monllin, C.B.E., Professor Rutherford Morrison, Dr. Eleanor Lorry, Dr. Russell Wells, Anonymous.
£1.—Miss Powning, Dr. Henry Bird, Dr. J. J. MacLennan.

REFORM IN MEDICAL EDUCATION.

[FROM A CORRESPONDENT.]

I.

For some time past, but especially during the last three years, the General Medical Council has been dealing with matters of the utmost importance in respect of the whole subject of medical education, and the trend of opinion shown in the reports presented to the Council and in the discussions on them, indicates the probability, indeed almost the certainty, of a very thorough revision in the teaching of medicine at the medical schools throughout the country. It is to be noted, however, that the relation of the Council to the universities and colleges is not such as to give it direct control over the curriculum. The licensing bodies have practical autonomy, so that the Council can only make recommendations which may or may not be adopted, the ultimate power of the Council being limited to advising the Privy Council to refuse registration of the licences or degrees granted by any body whose standards had become so unsatisfactory as to demand such drastic action. The Privy Council has never so refused. The Council itself, however, is mainly composed of representatives of the licensing bodies, and consequently its recommendations are likely to be in accord with the general opinions of the schools.

Though the JOURNAL has regularly published reports of the doings of the Council at its half-yearly sessions, it is proposed now, notwithstanding that it involves some degree of repetition of what has already appeared in the columns of the SUPPLEMENT, to review and summarize the proceedings for several years past with respect to the subject of reform in the existing scheme of medical education. The published minutes, reports, and discussions of the Council and its Education Committee are the sources of information.

THE TEACHING OF PREVENTIVE MEDICINE.

It will be convenient to deal first with preventive medicine; at the Council's May session of 1918 a motion was adopted:

"That it be remitted to the Education Committee (1) to report to the November session of the Council as to whether the Council should take any action towards promoting or systematizing the teaching of preventive medicine in the medical schools and in clinical hospitals throughout the country; and (2) to make such inquiry as the Committee may find necessary to enable it to report."

Before the end of the year the Committee, to which two *ad hoc* members had been added, issued to the medical schools a circular letter containing a series of queries regarding the teaching of preventive medicine. In submitting the queries it was explained that they were not intended to refer to the existing teaching of sanitary science for qualifications in medicine or for degrees or diplomas in public health. "What the Council has in view," it was said, "is rather the teaching of the schools and the clinical hospitals regarding the maintenance of health from birth onwards, the effect of conditions, including occupations, which are liable to cause illness, and the detection of the early evidence of disease in the individual, with a view to treatment of a preventive kind." The queries themselves give convenient exposition of what was in the mind of the Education Committee and the Council. Briefly, they refer to every subject of the curriculum, and they show the purpose of the Council to be that the prevention of disease, in addition to the cure of disease, should permeate the whole education of the student, from the preliminary sciences onwards to his entry into the profession of medicine. Of course, the ultimate object is that the education so acquired shall have its fruition in the preventive treatment of disease throughout the life of the medical practitioner.

At first sight, at least, it is not easy to perceive in what way preventive medicine can be taught in connexion with some of the subjects embraced in the curriculum, but the queries make clear what is in the mind of the Council, and some space must be devoted to noting the character of the questions propounded.

THE QUESTIONS.

Introductory Sciences.—Concerning physics, chemistry, and biology, it is asked whether these should include references to the later applications of these sciences to medicine; should the

teaching of any of them be continued at intervals through later stages of the curriculum, as, for example:

"Physics in direct relation to physical therapeutics, radiology, and electrical treatment?"

"Chemistry in relation to the normal changes of the body in health—that is, physiological or medical chemistry?"

"Zoology in relation to those conditions due to environment which affect the development of the normal organism, or in relation to the study of parasitology, with the view to eliminating sources of infection?"

Physiology.—As concerns physiology, the relation to health maintenance is obvious enough, and it is asked whether there should be fuller instruction in the physiology of normal human beings, and in the action of the organisms in normal human subjects—the exercise of normal functions as a condition of maintenance of health in respect of breathing, eating, drinking, exercise, rest, play, normal metabolism generally; also the physiology of normal childhood, adult life, and old age; the physiology and psychology of school life and the effects of over-pressure. In short, physiology constitutes, in old phraseology, the institutes of medicine.

Anatomy.—Here it is asked whether there should be fuller instruction in the conditions of growth and normal development in muscle, bone, nervous system, etc.; in the causes of imperfect development and physical degeneration; in anatomy in relation to orthopaedics, rickets, flat-foot; and to radiographic representation of structures, etc. It is further asked whether such teaching should be included in the regular courses or be given throughout the later years of the curriculum.

Psychology.—Another question, suggested by the war, is as to the far-reaching effects of intense emotion upon the functions of the sympathetic system and endocrine organs, and through them upon the working of every part of the body. Should medical students be taught psychology or the process of development of mental disturbance?

Pathology.—It is asked whether the teaching includes sufficient instruction in the early stages of the development of disease; whether etiology, as revealed in the history of individual cases, is sufficiently studied as a basis for the understanding of prevention; whether current teaching sufficiently brings out the distinction between stages of disease from which recovery can take place, and those which involve permanent changes and imperfect recovery or non-recovery.

Bacteriology.—It is asked whether the etiology of bacterial and other communicable diseases is sufficiently taught.

Materia Medica, Pharmacology, and Therapeutics.—Here it is asked whether current teaching deals sufficiently with therapeutics for the maintenance of health; whether it includes treatment by physical exercises and methods other than medicinal.

Clinical Courses.—In respect of this final and most important department of study it is asked whether it is desirable and practicable to include definite instruction in anatomy and physiology in their direct application to medicine as a basis for preventive measures; whether the teaching of clinical medicine extends beyond the immediate field of hospital treatment; whether instruction is sufficiently given in the preventive relationships of each several disease; in the means of preventing disease, individual and communal; in insidious disease, especially in the early stages; also as to attention to minor ailments; as to the significance of partial recovery in heart illness, kidneys, etc.; as to common septic infections; as to the relation of stunted growth and development to susceptibility to disease; as to diet in infancy, childhood and adult life; as to habits in regard to food and drink; as to the influence of occupation and exercise. In surgery similar questions are mentioned—the closer co-ordination of anatomy and physiology with surgery to provide a basis for knowledge of preventive measures; susceptibility to infection and the conditions which induce it; the prevention of septic infections; the care of patients after surgical treatment (rickets, surgical tuberculosis, etc.).

Special Subjects.—It is asked whether the courses include sufficient instruction in the preventive relationships of children's diseases, skin diseases, diseases of the eye, ear, nose, and throat, mental diseases, infectious fevers, venereal diseases, and tuberculosis.

Midwifery and Diseases of Infants and Young Children.—Here the questions are whether there is sufficient instruction in the prevention of disease in expectant mothers and in infants in connexion with child welfare schemes; in the maintenance of health during pregnancy; in the hygiene of infancy; the feeding of infants and young children; the effects of social conditions on infants' health in respect of milk supply, tuberculosis, rickets, diarrhoea, pneumonia, etc.; the sequelae of infectious diseases and the dangers of incomplete recovery.

Hospital Out-patient Departments.—Are these sufficiently adapted to and utilized for practical teaching of medical preventive care, and is full advantage taken of the material available for study of ailments at a stage before patients need to be sent to hospital or treated in bed at home?

Dentistry.—The Committee wish to know whether students receive sufficient instruction in the preventive relationships of dental disease and in the bearing of such disease on general health, and whether in the dental curriculum itself the preventive aspects of the subject are sufficiently enforced in relation to the causes of decay of the teeth.

In a concluding general note the Committee explain that they do not contemplate setting up new departments nor adding new

"An attempt should be made to direct the student's attention throughout his medical school course to the preventive aspect of medical practice. To this end it is suggested that useful work may be done in the preliminary, intermediate, and advanced periods of study. In the teaching of chemistry and physics stress could be laid on the relation of these sciences to the maintenance of a healthy environment, and in biology, upon

the influence of heredity upon good physique, and upon the hygienic effects of other living organisms upon man. It is not necessary that the teachers of these subjects should themselves be medical men, but as teachers in a medical school they should be encouraged to specialize in those branches of their sciences which have a bearing on personal hygiene and public health. There are obvious opportunities for teachers of anatomy and physiology to extend and accentuate those sections of their subjects which have a bearing on health and disease, and it might be possible to arrange special short courses of demonstrations by those junior teachers who are also working in the wards upon the anatomical and physiological relations of morbid conditions."

Concerning personal hygiene the school points out that:

"The main duty of a hospital is to afford medical attendance to persons who recognize that they are ill and apply for treatment of their ailments. Whatever changes may be made in the organization of the medical schools, regard must constantly be paid to the possibility of maintaining and increasing the capacity of the hospitals for carrying out their work." Yet—

"Inasmuch as many of the ailments for which treatment is sought are preventable, an opportunity is afforded, and is usually taken, to impress upon the individual patient the measures he might have personally taken to avoid his illness, and which, if he is ultimately cured or relieved, he should in the future take to prevent its recurrence or aggravation." And the school thinks that—

"It would no doubt increase the regularity with which this procedure is adopted and impress its importance both upon the patient and the students associated in his treatment if the custom of some physicians were more commonly used of handing to the patient, at the time of his discharge, printed instructions as to preventive measures applicable to his condition."

It further urges that:

"A great impetus would be given to preventive medicine of the personal hygiene type if in medical schools a special department for the medical inspection of apparently healthy persons were instituted. In such a department a member of the staff, assisted by senior assistants, would examine all applicants and inquire into their habits and environments, and give advice as to the measures to be taken to maintain a high or even higher standard of health. Such a department for children or adults would follow the line of infant welfare centres now established in connexion with some medical schools.

"The difficulty at the initiation of such a department would be to encourage attendance thereat. The introduction in the near future of the medical inspection of children attending continuation schools would perhaps afford an opportunity for an experiment to be made. The Board of Education might arrange that such medical schools as were willing to co-operate should be constituted as centres for the compulsory inspection of children attending their schools in the surrounding district. The young people who attended compulsorily under the scheme during school age should be encouraged to continue to do so voluntarily at the termination of their school period."

And it adds:

"If these and similar proposals are carried out it is believed that the attention of all those working in the school will gradually be drawn more and more to the importance of prevention, and that all teaching, both practical and theoretical, will be so permeated with the idea of prevention that practitioners trained under these conditions will be little likely to lose sight of its importance, whatever may be their lines of practice after qualification."

The above are only examples of the valuable material contained in the replies from the schools, but they serve to indicate the interest that is taken in the whole subject. As already stated, they seem to leave no doubt that preventive medicine will now occupy a larger place in the mind both of the teacher and of the student than ever it has done before throughout the whole of the medical curriculum.

(To be continued.)

THE scheme for the extension of the Royal Free Hospital is making satisfactory progress. The staff of the London School of Medicine for Women have generously increased their donation to the appeal fund for the extension of the hospital and medical school from £500 to £1,000. The extension of the hospital is to provide beds for that class of workers who live in small flats or lodgings, and are unable to afford the high fees necessarily charged by good nursing homes, but can afford the cost of their maintenance whilst sick (£4 per week). A few beds are now available for men and women at this charge, and twenty-five more beds will be ready early in the New Year. More beds for men, women and children will be provided as soon as funds permit. Donations and subscriptions should be sent to Sir Francis Leyland Barratt, Bt., honorary treasurer, Royal Free Hospital, Gray's Inn Road, W.C.1.

MOTOR NOTES FOR MEDICAL MEN.

By H. MASSAC BUIST.

DOCTORS AND TO-DAY'S NEW MOTORING LAWS.

So far as they relate to the taxation of motor vehicles the provisions of the Finance Act, 1920, come into force on New Year's Day, as do the provisions of the Road Bill which hurriedly passed the House of Commons and the House of Lords in December. These new conditions, which entirely recast the method by which revenue is levied from the motoring movement, the schemes governing licences, the exhibition of identification marks on vehicles, and so forth, concern medical men in various ways. These may be summarized by a reminder as to the obligations to which the members of the profession owning motor vehicles are liable.

Henceforth medical men are not concerned with rebates on petrol duty, because the tax on motor fuels of all sorts ceases. As far as privately owned passenger vehicles are concerned—and this is the category under which the machines of medical men come—the increased scale of taxation levied by way of licence for the use of such vehicles is the substitute for the fuel scheme. Some doctors own motor bicycles, others three-wheelers, some cycle cars, and some motor cars proper.

Broadly, motor bicycles and three-wheelers not exceeding certain weight limits are taxed by weight—a different scheme from that governing motor cars. But the initial method of procedure is the same in all cases. Hitherto, by the law that lapsed on the last day of December, 1920, it has been possible for a medical practitioner resident in Yorkshire to register a car in London and to buy his annual licence to use it at a post-office in Cornwall, it being necessary merely to take out locally a driving licence at the cost of 5s. a year. The new scheme of taxation does not concern itself with drivers' licences, which have still to be taken out locally. But from New Year's Day onwards the registration and the licensing authorities are centred in the same places. Owners are compelled to register their vehicles either in the districts wherein they reside or where they have most occasion to use their vehicles. Further, the yearly licence for the use of the vehicle has to be taken out locally, just as the driver's licence has always had to be taken out.

THE SCALE OF CHARGES.

Any private vehicle not exceeding 6 h.p., or which is propelled electrically, involves the payment by the owner of an annual licence fee of £6. For any privately owned motor vehicle exceeding 6 h.p. £1 will be payable for each unit, or portion of a unit, of horse-power according to Treasury rating. That is to say, the ownership and use of a 15.9 h.p. Treasury rating car involves the payment of an annual tax of £16, and so on. Many doctors, however, are still so fortunate as to have in use old cars which are serving them well. Some of these, of course, are constructed on engine principles which are rather hard hit by the adoption of Treasury rating in that the bore measurement is relatively large in comparison with the piston travel. Many such, however, will find a certain measure of relief in the section which reads:

"If any person proves to the satisfaction of the authority charged with levying the duty that he has paid in respect of any vehicle the duty chargeable under this paragraph (Section 1 of the 2nd Schedule of the Finance Act), and that the engine of the vehicle was constructed before the 1st of January, 1913 he shall be entitled to the repayment of 25 per cent. of the duty paid."

This, being interpreted, means that the owner of an old vehicle has a certain measure of relief on the assumption that it will not be giving him as satisfactory service to day as when he purchased it. Inasmuch as the tendency in the last seven years has been to increase the piston travel in relation to the bore measurement, the continued ownership and use of these older-style vehicles is not penalized, for 25 per cent. rebate is really a fair allowance.

NATURE OF LICENCES.

The Ministry of Transport has lately issued an official memorandum setting out the course to be adopted by car owners before New Year's Day. For the purposes of reminder, and for the sake of clearness, however, it will

be well to recapitulate the main heads of this memorandum as it concerns the medical man. Apart from the yearly licences of £1 per horse-power for cars, there will be issued—to be in force for three months from New Year's Day, from March 25th, from July 1st or from October 1st—quarterly licences each at a rate of 30 per cent. of the full annual duties. Quarterly and annual licences alike must be carried in a holder securely attached to the vehicle in a position in accordance with regulations whereby the licence can be seen from the rear side of the car. There are two types of licence cards, one circular and the other rectangular. Apparently the choice of type is at the option of the user, the general trend of opinion at the moment being evidently in favour of the circular type, which is neater and more in keeping with the badges of the R.A.C., the A.A., and so on. Each licence is printed on a stout paper card of colour according to the period for which it is to run. Thus the annual licence for this year will be in blue. The first quarterly licence will be yellow. The colours for the second, third, and fourth quarterly licences have not yet been settled. The licence has to be exhibited in a conspicuous position on the rear side of the car, being on, or attached to, the wind screen, or on the outside of the fore portion of the vehicle, in line with the driver's seat. It must be contained in a metal holder of weather-proof construction. Types of holders, designed specially to enable the licence to be exposed, have been approved by the Ministry, and are being standardized by the accessories industry.

METHODS OF PROCEDURE.

The first thing the owner of the motor vehicle has to do is to obtain from his local money order office, or from the registration authorities in the area of his domicile—the local postmaster will give the address on request—an application form. Having filled this in, he sends it to the registration authority in his own area, together with a remittance for the requisite amount. This form relates to the registration of his vehicle under the new regulations; it also constitutes the application for the licence, whether yearly or quarterly. Provided the owner takes care to register the letter in which he sends the form his responsibility is practically at an end. If he can prove that a licence, or an application for the same, together with remittance, is in course of post, it is beyond the power of the authorities to make out a case that he has striven to evade the law. Of course, a considerable amount of turning over is being involved at this period by reason of the localizing and co-ordinating of the registration and the licensing authorities, and of the adoption of the principle of local registration. In the case of cars already licensed, and therefore carrying number plates often issued in areas where the car is neither owned nor used, the registration will remain in force when the necessary transfer of particulars has been effected. But all new cars taken into possession from now onwards have to be registered in the district in which the first owner resides, as distinct from the very general practice hitherto, whereby cars have been registered, to the number of thousands, in the district where they have been built. In exchange for the form and remittance the vehicle owner is entitled to receive what is technically styled a continuing document in the form of a registration book, together with a licence card, which has to be placed on the vehicle, as already indicated. By contrast the registration book, which contains the history of the vehicle and is stamped each year—or each quarter, as the case may be—to show at a glance that the fee has been paid, must be kept by the owner in some secure place, but, preferably, not on the car. It may be inspected by the police at any reasonable time. But the owner is not required to carry it with him when motoring on his vehicle, as he is required to carry his driving licence when driving. The registration book is the property of the owner of the vehicle so long as he remains in possession of it. When he sells the vehicle the book passes to the new owner through the one or two—as the case may be—registration authorities concerned. When an owner sells a car he must notify his registration authority and return him the licence and the registration book issued in respect of that car. The local authority will then enter up in the book the date of the transfer of ownership and, on receiving application—direct from the new owner if he is

resident in the same neighbourhood, or, alternatively, from the registration authority in the neighbourhood in which the new owner resides, and to whom the new owner will apply—transfer that registration book, either direct to the new owner, or to his registration authority, which, in turn, will issue it to the new owner after having entered up all the details. In short, the registration book is the history of the vehicle. It remains in possession of the owner of the car for the time being. The complete particulars in it are reproduced and kept permanently in the books of the licensing authorities.

TRANSFERS AND SHORT-TERM LICENCES.

By contrast with former procedure, in the motoring laws which have now come into force the licence primarily concerns, not the owner, but the car. Thus, if the writer takes out a yearly licence for his car to-day and sells his vehicle to the reader in July, the reader, as buyer, having completed formalities, enjoys the benefit of that licence till December 31st, 1921. Hitherto the practice has been that if one sold one's car at any period of the year and bought another vehicle not exceeding the same Treasury h.p. rating, there was no occasion to take out a second licence for the use of the car. Now, however, if, having sold his car—therefore having passed the licence on—the writer wishes to buy a new one in the middle of the year, he must pay another horse-power tax in respect of whatever period of the year remains unexpired. For example, if he wishes to use it from an early period in July until the end of the year, then it will pay him best to take out two quarterly licences, each at 30 per cent. of the rate obtaining for the whole year, so that he would get off with the payment of an aggregate of 60 per cent. for six months' use of the car.

In the case of three-wheelers, this licence must be fixed "in a conspicuous position on the rear side of the vehicle, and visible at all times by daylight, to an observer standing at the rear side of the vehicle—whether the vehicle is moving or stationary."

Forms of application for licences and for the tax are obtainable from any money order office on New Year's Day. It may be pointed out that if the licence is not fixed in the legal position, or if, being so fixed, it is in any way obscured or rendered or allowed to become not easily distinguishable, the person driving the vehicle will be liable on summary conviction to a penalty not exceeding £20 for the first offence, the penalty for subsequent offences being limited to £50. If, however, the person charged proves he has taken all steps reasonably practical to prevent the licence card being obscured, or rendered not easily distinguishable, he will not be liable to be convicted. One does not anticipate that once the new scheme has been running for twelve months its working will be found any more irksome than the old. In fact, it should be rather simpler in face of the provision in the Roads Bill to the effect that in the case of any car to which a registration number has been allotted prior to January 1st, 1921, that number shall be treated as having been assigned to the given car under the new regulations and no new number shall be assigned to such a car. To have proceeded in any other way would have been foolish in face of the fact that, though cars have now to be registered locally, often they will be sold to owners outside the given locality, consequently some cars will always be found about the country carrying number plates other than those of the locality in which their present owners reside and in which they are being used. The new form of taxation does not concern the driving licence, which will have to be taken out, as hitherto, at the price of 5s.

Considering the many minor modifications made week by week, if not day by day, in the details of procedure ordered by the Road Board, when in any doubt on a point it is advisable to inquire at the local money order office or at the local registration office.

THE National Association for the Prevention of Infant Mortality will hold its second English-speaking Congress on Infant Welfare in London on July 5th, 6th, and 7th. The following are among the subjects to be discussed: Residential provision for mothers and babies; inheritance and environment as factors in racial health; the supply of milk, its physiological and economic aspects. Further particulars may be obtained from the Secretary at 4, Tavistock Square, London, W.C.1.

British Medical Journal.

SATURDAY, JANUARY 1st, 1921.

GALEN.

CHARLES LAMB, in his list of *biblia a-biblia*, assigned a prominent place to "the histories of Flavius Josephus, that learned Jew," and we make no doubt that had Kühn's edition of Galen (a new book when Elia wrote) come his way, it would have fallen under a like condemnation, being certainly a work which "no gentleman's—at least no physician's—library should be without."

Since the days of Elia there has not been any noticeable increase in the demand for Galen's writings. So far as we know, there is but one London medical library from which Kühn's edition (the only modern edition) can be borrowed, and we have never found any great difficulty in securing a volume there. Epidemiologists, and even statisticians, discover that the fame of Sydenham was not unmerited; nobody has yet proved that Galen was an early biometrician with correct views on the periodicity of disease.

At a recent meeting of the Historical Section of the Royal Society of Medicine Dr. Major Greenwood endeavoured to decant the ancient wine into new bottles. Dr. Greenwood, of course, did not wholly avoid the snare which, as he pointed out in a lecture printed in our columns last year, entangles the feet of most students—the risk of finding in ancient writings what one brings to them. Perhaps his attempt to discern in Galen *De Temperamentis* a Bravais-Pearson correlation surface, smacks overmuch of the Puseyite who, according to Macaulay, proved that the *Pilgrim's Progress* was composed in the interest of Tractarianism. Then, again, one need not go very far afield to discover the secret of Galen's medical dictatorship. In doing so Dr. Greenwood for once forgot to take the cobbler's interest in leather. The explanation is, as Dr. Singer remarked, statistical; more than 50 per cent. of surviving Greek medical literature is the work of Galen; it would have been strange had Galen not dominated an authority-loving posterity. Yet this is not the whole explanation, and, although Dr. Greenwood disclaimed any attempt to reconstitute the personality of Galen, he did succeed in conveying an impression of it which, whether just or not, was vivid.

Freud himself psycho-analysed Leonardo da Vinci; others who, let us charitably suppose, have at least read the works of Freud, have psycho-analysed Wordsworth, Shelley, and even Homer. Galen may be suggested as an admirable subject. Dr. Greenwood pointed out that in Galen we find interwoven the intellectual and moral characteristics of a Greek of the empire, seen at their best in Lucian, at their worst in *Graculus esuriens* of Juvenal, with those of the great men of Plato's day. We have abundance of epigram, usually spiteful, sometimes witty, much dialectic, the wisdom of Nigrinus rather than of Socrates. But there is something more; something which we admire in Hippocrates. Galen, for all his hair-splitting realism (in the mediaeval sense), preached a doctrine of unity in disease. His theory of procatarxis, his teaching that in the innate structure and functions of the body and the variations imposed thereon by the

atmosphere, by habits of life, by all the phenomena of existence, are to be found the "causes" of disease, is still of value.

Dr. Greenwood pointed out that this philosophy of disease was also embraced by the enthusiasts of the early Victorian epoch. Galen's faith in temperance and moderate exercise, Chadwick's faith in better housing and proper "drains," translate into different dialects the same idea. Galen attached more importance to "seeds of pestilence" and to miasm than did Chadwick; but both agreed in attributing to the totality of conditions a unitary effect. Galen, a nimble-minded Greek, could easily have been taught the bacteriological theory of disease by a traveller on Mr. Wells's time machine. The differentiation of bacteriological strains would have charmed him; he would infallibly have carried it much further than we do. But it would have been altogether impossible to convince him that disease can be conquered by successively or simultaneously immunizing individual citizens against a series of specific "seeds of pestilence." He would have obstinately maintained that to secure a sound body obedience to his principles *de sanitate tuenda* is necessary, and that without such obedience no lasting change in the general level of health can be secured.

Dr. Greenwood argues that Galen had a case, that the epidemiological events of the last few years point to a need for reconsidering our philosophy of disease. We have not to argue that case here, and those who seek from Galen enlightenment in our present difficulties will not perhaps—as Dr. Greenwood for his own part admitted—get so much as they desire. It is, however, a pity that none of the more strictly professional writings of Galen have been translated into modern English. Dr. Block's edition of Galen on the Natural Faculties (in the Loeb series) gives a good idea of Galen's general physiology. Perhaps one day *De Febrium Differentiis*, *De Sanitate Tuenda*, and *De Temperamentis* will also be made accessible.

We cannot live on the classics; Galen will never more be read by medical students even at Oxford. But it is strange that the writings of one who filled so large a space in medical history should be far less accessible than those of any other extant Greek author of his period.

HOSPITAL PROBLEMS.

THE difficulty of finding adequate hospital accommodation for those in need of it is no new thing; it was realized long before the dawn of modern medicine and surgery. Writing in 1752, Fielding said "The properest objects (those I mean who are most wretched and friendless) may as well aspire at a place at Court as at a place in the Hospital." The necessities are better off nowadays in that respect, but the hospital problem remains with us, and in some ways is more urgent now than ever before. The war aggravated the trouble while obscuring its signs and symptoms. But towards the close of 1919 there began a great stirring of opinion in regard to civil hospitals, and interest has grown during the past twelve months. The financial plight in which most of our voluntary hospitals find themselves has been brought home to the public; and, side by side with that, new ideas about medical charities and their relation to modern ways of life have been taking root in the minds of the public and of the medical profession. That more hospital accommodation is needed seems beyond question, and most people agree that the voluntary system should be reshaped but not destroyed. The problem is how to adapt the

system to meet present-day needs and notions without breaking the spirit that informs it. Dr. Addison, Minister of Health, has said this many times in the House of Commons and elsewhere; once last year he went so far as to declare that no Minister of Health in his senses would set about to destroy voluntary hospitals. We do not doubt his sincerity, but in these times a minister's good intentions are of small account when his department and himself are under the fierce searchlight of the newspaper press, which, for good or for evil, is a force that has to be reckoned with.

The idea of tackling the hospital problem early was praiseworthy, but in the light of what has since happened it seems clear that an error in parliamentary tactics was made; someone blundered, as we ventured to suggest at the time. On August 16th, 1920, just before the adjournment, Dr. Addison introduced into the House of Commons a medley of legislative proposals in regard to housing and incipient mental disorder and to various matters (including hospital provision) having more or less to do with public health. It was entitled the Ministry of Health (Miscellaneous Provisions) Bill, and Clause 11 sought to extend the powers of county borough councils so that they might supply and maintain hospitals, contribute to voluntary hospitals, and maintain Poor Law hospitals within their area. In the interval between the introduction of the bill in the Commons and its summary rejection in the Lords, on December 14th, 1920, this clause came in for a great deal of adverse criticism. It was interpreted by some as the first step towards imposing bureaucratic control upon the hospitals of the country and towards the destruction of the voluntary hospital system. The bill had rather a rough passage through the House of Commons; a number of clauses were dropped during the Committee stage, and Clause 11 was modified. The apprehensions felt by the medical profession in regard to the hospital clause were placed before the Ministry by a deputation from the British Medical Association on November 1st, 1920. On that occasion the spokesmen of the medical profession took their stand on two main principles: the need for central medical consultation on the main grounds of policy, and the need for local medical consultation in regard to the details of local schemes. The Minister, in his reply, expressed the wish, that there were some body representing the profession generally with which general principles could be discussed during the formative stages of any large hospital policy. He agreed further that local advisory committees might well be set up in connexion with schemes for hospital provision. The composition of a central committee representative of the whole medical profession is not easy to determine, but steps have already been taken by the Association to give effect to the hint. Before the bill met its fate in the Lords it was urged upon Dr. Addison by members of both Houses that every effort ought to be made to sustain the voluntary system, and with this end in view he agreed to appoint an independent committee of five to consider the financial position of the voluntary hospitals throughout the country, and to make recommendations thereon at an early date.

The reference to the committee raises questions of the highest moment to the medical profession, more particularly to those attached to the staffs of voluntary hospitals. On July 1st, 1920, when events were not moving quite so fast in the hospital world, the British Medical Association had the foresight to hold a conference during the Annual Meeting at Cambridge to consider the relation of the honorary staffs of

voluntary hospitals to the treatment of State-supported patients. There was a large attendance, and the chairman, Sir Cuthbert Wallace, wisely allowed full latitude for discussion. In the result a resolution was carried with one dissentient, approving the policy of the Hospitals Committee of the British Medical Association in regard to the remuneration of voluntary hospital staffs for work done on behalf of State-aided patients, and directing that the subject should be brought to the notice of the governing bodies of these institutions. On that occasion the general subject of hospital finance was not debated. The outcome of the conference was in direct line with the action already taken by the Association on behalf of members of hospital staffs in the case of the treatment of was pensioners.

The Cambridge conference was followed by others throughout Great Britain, and in that way the attention of those most concerned was drawn to this aspect of the hospital problem. The conference held in London on December 21st, 1920, and fully reported in this week's SUPPLEMENT, had a wider field for discussion and marked a further stage in the shaping of hospital policy. The chairman, Sir James Galloway, described it as the first real interchange of hospital staff opinion upon the problem of finance, and the greater part of the day was given up to this topic. The short discussion on the attitude of members of medical staffs of hospitals towards paying patients may be regarded as a sequel to the Cambridge debate. It is significant of how quickly opinion moves in these times that a proposition rejected at Cambridge when put in bald terms should have been accepted in principle six months later in London. On July 1st, 1920, Dr. Astley Clarke of Leicester moved that the time was ripe for the payment of honorary staffs for all services rendered in voluntary institutions, by way of an honorarium on the percentage basis of the expenses of the hospital. This was lost by a large majority, five only voting in its favour; yet on December 21st Dr. Astley Clarke carried a resolution to the effect that should "decisions be taken which would lead to patients paying, in part or in whole, the hospital maintenance fees, either individually or by some contributory method, or with the addition of rate aid or State aid, or by a combination of two or more of these methods, a percentage of all such payments should be passed into a fund which could be allocated in any manner which the honorary-medical staff might determine." Despite some objection to the question-begging adjective "honorary," this resolution was adopted unanimously.

On the main subject of hospital finance the conference in London recorded its faith in the voluntary system as a boon to the public, to medical science, and to the medical profession. The opposition, valiantly led by Dr. Peter Macdonald, numbered four in a meeting of one hundred and fifty. A motion that necessitous persons should continue to be treated free was adopted without discussion. It was further agreed that voluntary hospitals ought not to be subsidized by the local rating authorities, save in so far as payment is made for the examination and care of patients for whom such authorities are responsible. On the other hand, the principle was accepted that in times of financial difficulty the central Government should subsidize voluntary hospitals by way of contributions proportional to the income received by the hospital in question from voluntary and other contributions, such subsidies being made through some central fund. The view that employers and insurance companies should do much more in support of the

voluntary hospitals, to which they owe so much, was accepted. In double harness, as it were, with this resolution, another was passed declaring that patients in voluntary hospitals who are not necessitous should contribute during treatment towards the cost of maintenance. This principle, if applied in the absolute form expressed in the resolution, may have consequences more far-reaching than perhaps all members of the conference fully appreciated. In industrial centres, especially in the North of England, where workmen's contributions constitute 50 and even 90 per cent. of the hospital incomes, it is hardly to be expected that the workpeople would agree to make a weekly contribution during health and also to pay for maintenance during illness. As the Chairman of Council of the British Medical Association pointed out, the fund formed by the weekly contributions, which is now paid to hospital governors, would, under the plan suggested, almost certainly be retained by the representatives of the workmen to pay the maintenance charge made by the hospital.

Upon the question of provision for paying patients in voluntary hospitals the conference recorded its opinion that no fixed rate of payment for professional services to such patients should be laid down, the fee remaining (as at present) an arrangement between patient, family physician, and consultant.

The concluding resolution was a vote of confidence in the Hospitals Committee of the British Medical Association as the convener of such conferences, and an acknowledgement that the questions discussed are as yet far from solution. This acceptance by voluntary hospital staffs of the machinery of the British Medical Association marks the consolidation of a policy from which much is to be hoped in this and coming years. The hospital system of the country is now being remoulded, and it is essential that during this process means should exist, through the organized machinery of the profession, for bringing together the best brains in it for the discussion of the many important problems arising.

CENTENARY OF THE ACADEMIE DE MEDECINE.

THE celebration of the centenary of the Academy of Medicine of Paris was formally begun by a solemn ceremony on Monday, December 20th, at 3.30 p.m.; M. Millerand, the President of the French Republic, was in the chair. The President of the Academy, M. Laveran, first read an address; then the new perpetual secretary of the Academy, Professor Achard (who has just succeeded in this office the late Professor Debove), called on delegates to present their addresses. Owing to the large number of delegates (113), of whom Switzerland sent 25, Great Britain 16, Belgium 11, Holland 6, Italy 6, Venezuela 6, the United States of America 5, Denmark 4, Chile 4, and Greece 3, one representative only of each country was called upon to present his address, though England, Scotland, and Ireland were counted as separate countries for this purpose. The Central Empires, it is hardly necessary to mention, were not represented among the delegates. In reply Professor Achard delivered a short but eloquent message of welcome, and, after the Minister of Public Instruction, M. Hounorat, had given an address, M. Millerand dissolved the meeting. On Tuesday morning, December 21st, Professor Vaillard reviewed the part played in the last 100 years by the Academy of Medicine in the evolution of public health, and was followed by M. Hanriot, who commemorated the benefactors of the Academy. In the afternoon Professor Chaffard summarized the work done in medicine by the Academy, dwelling much on Villemin's researches on tuberculosis and Pasteur's epoch-making investigations in connexion with microbic diseases. At 5.30 p.m. the

delegates were received by the Mayor of Paris at a reception given by the municipality at the Hôtel de Ville. On Wednesday-morning M. Camus described the influence of the Academy on vaccination, and M. Meillère discharged the same duty with regard to hydrology. In the afternoon the past President, Professor Delorme, gave an exhaustive historical review of surgery in relation to the Academy during the century 1820-1920. The celebrations closed in the evening with a banquet at the Hôtel Palais d'Orsay, with M. Laveran, President of the Academy, in the chair. The cordial hospitality given to the delegates was emphasized by the gift of a beautiful memorial medal, designed by M. Paul Richer.

SILICOSIS AND TUBERCULOSIS AMONG MINERS.

IN his annual report for the twelve months ending July 31st, 1919, Dr. W. Watkins-Pitchford, chairman of the Miners' Phthisis Medical Bureau, reports over 32,000 statutory clinical examinations and investigations; in addition the board made 1,400 examinations for military service, and for five weeks they gave their whole time to attendance on patients suffering from influenza during the epidemic. The prevalence of pulmonary tuberculosis, whether "pure" or complicated by silicosis, as revealed at the periodical examinations of 15,000 miners of European descent, was at the rate of 1,141 per 100,000, as compared with 1,267 and 909 for the two preceding years respectively. The prevalence rate of silicosis, whether in its pure form or complicated by tuberculosis, was 5,532 per 100,000, as compared with 5,602 and 5,595 for the two previous years. As ascertained at the periodical examinations, the attack rate of tuberculosis not complicated by silicosis was 255 per 100,000, as compared with 259 for the preceding year. In one case only was pulmonary tuberculosis detected at periodical examination of a person who had passed the "initial" examination of the bureau. The apparent production rate of cases of non-complicated silicosis detected at periodical examinations was 2,480 per 100,000, a figure more than double that of the previous year; it is pointed out, however, that a considerable number of these miners had lately returned from active service, and not all had developed their condition during the year under review. The prevalence rate of tuberculosis in combination with silicosis, as detected at periodical examination, was 869 per 100,000—almost the same as in the previous year. The statistics given refer to persons of European descent; among 172,000 native labourers, of whom 129,000 were employed underground, tuberculosis without silicosis was found in 789 instances, giving the low prevalence rate of 458 per 100,000, while tuberculosis in combination with silicosis was encountered in 378, or 219 per 100,000. It is the unanimous opinion of the bureau that in assisting the formation of a just decision as to the presence or absence of silicosis, and also for the diagnosis of all but the very earliest cases of tuberculosis, it is of paramount importance that a technically satisfactory radiogram should be available. During the twelve months 172 miners were admitted to the wards for observation extending from two to five days. During the 15,000 periodical examinations of working miners of European descent the opinion was formed in 165 cases that the person's health was likely to be endangered by a continuance in underground work; of these, 135 were judged to be in danger of developing tuberculosis, including 102 who were already silicotic; 24 were cases of heart weakness, 2 of chronic malaria, and one each of chronic bronchitis, empyema, cancer, and epilepsy. In view of the observation that tuberculosis affecting the silicotic miner is relatively non-communicable to healthy persons, preliminary experiments were made with the object of detecting a possible diminution in the virulence of the *Bacillus tuberculosis* after it has been propagated in silicotic lung tissues. In guinea-pigs, however, whether the bacilli had been derived from silicotic cases or from the subjects of ordinary

pulmonary tuberculosis, it was found that the animals injected developed tuberculosis with equal rapidity and with the same characteristic distribution.

FLAVOURING AGENTS IN MEDICINES.

THE Insurance Committee for the County of Stirling has proposed to take action in connexion with the routine use of flavouring and sweetening agents in doctors' prescriptions. At a meeting of the Committee on December 16th a letter was read from the Scottish Board of Health in which it was stated that while on the one hand the Board could not refute the argument that medicine made pleasant was more likely to be taken regularly, yet on the other it suggested that the use of flavouring and sweetening agents would tend to foster the drug habit. The Board believed that the average insured person goes to his doctor in order to get well as quickly as possible, and is therefore prepared, as an intelligent person, to obey instructions as to treatment. Though it believed that only a very small minority of patients needed to have medicine made palatable the Board did not suggest that it was possible to discontinue the use of flavouring and sweetening agents entirely; it, however, desired that the considerations set out should be placed before the Panel Committee, together with a reference to the memorandum on the rate of medical remuneration under National Insurance by Sir Clifford Allbutt, President of the British Medical Association, which was submitted early in 1920 to the Arbitration Board. The particular passage quoted from the President's memorandum (which was printed in full in the SUPPLEMENT of February 28th, 1920, p. 46) was as follows: "And, last, not least, the doctor requires to have time for the customs of private practice, namely, instead of curt and dictatorial visits, patient and explanatory conversations, such as to lift the patient out of the pill, plaster, and bottle superstition, and up to a rational conception of the nature of the disease, its prognosis, and the means of its prevention." The Insurance Committee expressed itself satisfied that the Stirlingshire doctors were endeavouring to keep the cost of prescriptions down to the lowest possible figure. But there is something droll in this solemn discussion of the ancient question whether medicines should be nice or nasty. There are some, even among the medical profession, who think that the nastier the medicine the more effective it sometimes is. The President's dictum does not, in fact, deal with the point; Sir Clifford Allbutt was urging an appeal to the patient's reason, for his help in the prevention and treatment of disease. He was not at all concerned to recommend that the pill or potion, when it had to be prescribed, should be nasty.

DIPHTHERIA CARRIERS.

COTHRIE, GELIEN, and MOSS have undertaken an exhaustive investigation of the diphtheria-carrier problem, and now supplement their observations published in 1912 by results of far-reaching importance as regards the practical significance of the carrier state and the question of how, from the point of view of the community, diphtheria carriers should be dealt with.¹ In February, 1912, a single throat-swab from each of 800 children attending one of the public schools in Baltimore revealed diphtheria bacilli in 85 children, or 10.6 per cent.; a re-examination of the same 800 children three months later gave positive cultures in 69, or 8.6 per cent.; and the number of children yielding positive cultures at either one or the other examination was 144, or 18 per cent. Virulence tests, as shown by injection of cultures into guinea-pigs, a positive result being reported when death occurred with characteristic lesions within four days, were carried out with diphtheria bacilli from 99 cases and 9 were found to show virulent bacilli. From further swabbing of some of these 800 children

15 more carriers were discovered, bringing the total up to 160. Only 11 of these 160 carriers gave a history of having had diphtheria, and none within the previous three years; while under observation none of them subsequently developed diphtheria. Fourteen of the carriers gave a history of exposure to diphtheria at periods varying from one to twelve years previously. Careful inquiry failed to find any example of the disease arising among the contacts of the 160 carriers. In order to determine how long diphtheria bacilli persist in the throats of persons with positive cultures, but without clinical evidence of the disease, 50 of the carriers mentioned above were examined at intervals of two weeks for three months; at the end of this period six only were positive. With the object of throwing light on the question whether or not diphtheria bacilli in the throat can undergo a change in virulence—that is to say, whether virulent bacilli can become non-virulent or non-virulent bacilli become virulent—a remarkable experiment was performed on five healthy persons proved to be free from diphtheria bacilli by daily cultures over a period of two weeks; their throats were then inoculated with a pure culture of non-virulent bacilli, and after that daily swabs were examined for some weeks, then swabs were taken at intervals of a few days for three months, and subsequently at longer intervals for about fifteen months; some of these five individuals became carriers, but none ever showed virulent bacilli or suffered from symptoms referable to the diphtheria bacilli in their throats. A series of observations on the cultural and staining reactions showed that virulent and non-virulent diphtheria bacilli are exactly alike, and can be distinguished only by the toxin-producing power possessed by the virulent bacilli, as shown by the guinea-pig test. The other members of the diphtheria group are readily differentiated from the diphtheria bacilli, and are without any pathogenic significance. The important conclusions from these observations may now be briefly summarized: the diphtheria bacilli in a majority of healthy (that is, not "convalescent" or "contact") carriers are non-virulent; non-virulent bacilli cannot cause diphtheria; there is no proof that non-virulent bacilli can become virulent; and therefore carriers of non-virulent bacilli are not a menace to others or to the community at large, and interference with their liberty is unwarranted. It may be advisable to isolate carriers until the question of virulence of their bacilli has been decided, but, if the culture proves non-virulent, further detention of the carrier is unjustifiable. No doubt time and expense are entailed by the guinea-pig test, and a simpler and less expensive one is urgently needed; but this drawback is less serious than the economic loss and inconvenience incurred by needless isolation of the carrier of non-virulent bacilli. On the other hand, the carrier of virulent bacilli occupies an entirely different position.

THE CAMPAIGN AGAINST VENEREAL DISEASE.

THE commission, consisting of Dr. Rupert Hallam, Mrs. C. Neville Rolfe, and Miss E. O. Grant, which has been sent out by the National Council for Combating Venereal Diseases, with the authority of the Colonial Office, to study the social conditions and the steps to be taken locally to combat venereal disease in the East, has had a warm welcome during its journey across Canada. The Canadian Council for Combating Venereal Disease and the public health authorities took the opportunity which the presence of the commission afforded to conduct a vigorous campaign of instruction, and to enlist public support throughout the Dominion; the assistance given by the press greatly added to the success of these meetings. A large meeting was held at Toronto on November 8th under the chairmanship of the Hon. Mr. Justice Riddell, and a resolution was passed urging that the Ontario Council should be reorganized on the lines of the National Council in Great Britain, so that closer co-operation might be obtained between the Government

¹ C. G. Guthrie, J. Gelien, and W. L. Moss: *Bull. Johns Hopkins Hosp.*, Baltimore, 1920, xxxi, 338-403.

and provincial and municipal authorities. Before the commission left for Hong Kong and other eastern ports it was able to convene a meeting at Victoria of representatives of practically every organization in British Columbia, and a committee was formed to assist the Canadian Council in attacking venereal diseases as a general health problem.

EPIDEMIC HICCOUGH.

DURING the last few weeks the Paris correspondents of the daily newspapers have mentioned on several occasions the prevalence of hiccough there and have noted that the disorder has incapacitated several public men. An account of the symptoms of what has come to be called epidemic hiccough was given by MM. J. A. Sicard and J. Paraf to a meeting of the Société Médicale des Hôpitaux de Paris on December 3rd, 1920, and at a subsequent meeting it was reported that forty cases had been noted during eight days among 3,000 male factory hands at Lille. The malady appears to show a particular affinity for the male sex; of Sicard and Paraf's twenty-seven cases, one only was a female. Although occasionally preceded by a slight degree of muscular stiffness, brachial or cervical neuralgia, epigastric discomfort, or febrile malaise, the attack as a rule appears quite suddenly in persons who are otherwise in good health. Usually its duration is two or three days and the temperature is little raised, if at all, but Netter had one patient whose temperature exceeded 102°; in this case the illness lasted six days. The hiccough occurs in rhythmic crises lasting from half an hour to an hour and a half, and separated during the daytime by intervals of similar duration. During the attack the spasms occur at the rate of six to eight a minute; the crises are not usually frequent during the night, and there is little insomnia. No cases of relapse or recurrence, or of any complication, were noticed. In two cases the cerebrospinal fluid was found to be normal. With regard to treatment, analgesics, including morphine, were often ineffective, but in certain cases the spasms could be inhibited by compression of the eyeball, rhythmic traction on the tongue, or the application of an icebag to the side of the neck. The physicians of Paris appear to have little hesitation in connecting this curious epidemic with that of encephalitis and its myoclonic manifestations. Fortunately, in the cases reported up to December 3rd, hiccough was the sole serious manifestation, and the course of the malady was entirely benign; in view, however, of the polymorphism of epidemic encephalitis, and of its widely different modes of onset, it is right to maintain a certain reserve with regard to the prognosis of epidemics such as the one recorded in Paris. Possibly Sicard and Paraf are right in their conjecture that cases formerly described as hysterical or neuropathic hiccough, and also certain epidemics of chorea major recorded during the Middle Ages, may have been connected with a coincident or antecedent epidemicity of encephalitis.

PRIZE IN OPHTHALMOLOGY.

MR. W. EDMONDS and Miss S. Edmonds, of Wiscombe Park, Colyton, have founded a prize in ophthalmology in memory of their brother, Nicholas Gifford Edmonds, Lieutenant 2nd Black Watch, who fell at Magersfontein on December 11th, 1899. The prize, of the value of £100, will be awarded every two years for the best essay on a subject dealing with ophthalmology and involving original work. The competition is open to all British subjects holding a medical qualification. Subject to certain legal conditions, the management of the prize will be in the hands of a committee nominated biennially by the Medical Board of the Royal London Ophthalmic Hospital, which will select the subject of the essay and elect two examiners. The winner of the prize will have the option of giving a lecture on the subject at the Royal London Ophthalmic Hospital. The Middlemore Prize of the British Medical Association, awarded triennially on very

similar lines, has rendered valuable service to ophthalmology, and many of the Middlemore Prize essays remain standard works. It may certainly be expected that the generous gift now made will also serve as a strong stimulus to original work. There cannot be too many such incentives to break away from routine in professional life, and to stimulate initiative; many men have originality and power of investigation, but from lack of stimulus do not settle down to any definite line of research; the setting of a concrete subject is often all that is required to fire a man to carry out a valuable piece of work. As the subject of the essay will be announced two years before the award, ample time will be afforded for studying the literature, for thorough observation, and for carrying out experiments before sitting down to the actual composition of the essay. By their generous liberality Mr. and Miss Edmonds place the profession under a deep debt; their wish in founding the prize is that suffering may be alleviated, and it may be confidently anticipated that this end will be attained.

THE WAR EMERGENCY FUND.

WE are informed that the Executive Committee of the War Emergency Fund, at its meeting on December 21st made several substantial grants to defray, in whole or in part, the school fees of the sons of medical men who left their practices to take up commissions in H.M. Navy or Army during the late war, and who, after resuming civil practice, find themselves in temporary financial difficulty owing to their war service. The Committee is prepared to make similar educational grants for the daughters of such medical men. Applications for such grants should be made to the Honorary Secretary, War Emergency Fund, 11, Chandos Street, Cavendish Square, London, W.1.

A BILINGUAL Congress in Radiology will be held in London in the middle of April next. The Congress will last three days, and on each day there will be papers and discussions in each of the three subjects—radiology, electrolgy, and physiotherapy.

Medical Notes in Parliament.

The Parliamentary Session.

VARIOUS reasons may be assigned why Parliament, in the session just ended, has not fulfilled the high hope of the King's Speech of last February. Perhaps the simplest and broadest explanation may be provided by the psychologist, who would say that the fault lay not particularly in men or measures or circumstances, but in all three—that is, in the inevitable difficulty of quickly reforming habits of mind and procedure which had been set up for the war and temporarily hardened.

This explanation applies to the somewhat jerky way in which Cabinet Ministers in their utterances have dealt with both foreign and domestic policy, authoritatively and unauthoritatively, just as during the war they acted sometimes collectively and sometimes on their own initiative to meet the emergency. It accounts also for the defective working of members of Parliament, who, under the system developed for the war, have had to distribute themselves on various Grand Committees upstairs, like irregular bodies of quicksilver, and have thus been tempted to neglect the House itself. Their attendance in that place has often been poor, and discussions have been left to a few members both for speech and for hearing; so it has happened that the House itself has lost much of its former authority and distinction. As for the measures put forward by the Government, they have evoked the criticism which architects make of transition periods; they have lacked character and strength in gathering up purposes and plans left over from the war, and they have not been fully designed for the new circumstances of peace. What was needed in the change over was leisure and deliberate thought. Instead, the war habit of mind and the pressure of circumstances have led to an attempt to do too much in the time. Thus, there have been diffused activities and a certain waste of energy

and want of clearness of expression. It must be recognized that this was almost inevitable; but none the less it is desirable that the causes for the very partial success of the session should be frankly faced, so that they may be corrected as soon as conditions permit.

While these reflections cannot be avoided, it is due to the Government to remember that several measures of great importance have been enacted, and that brave attempts have been made to carry through others. In addition, a number of smaller matters have been usefully dealt with in minor bills, and the whole scheme of administration has been in process of gradual revision. Perhaps the Coal Mines Act, although its passage is now almost forgotten, will rank first in value in history owing to the understanding reached between owners, miners, and the State. What will emerge out of the Home Rule Act nobody professes to be able to say; but a bill which is designed to enable the setting up of two parliaments and to rearrange all sorts of relations between Ireland and Great Britain necessarily requires a great deal of care—none the less because the Opposition, disagreeing with the proposal, declined to have anything to do with it. The Agricultural Act involved other delicate matters of settlement between the various interests engaged in the cultivation of the land, and the controversy excited in both Houses sufficiently showed the difficulty of the problem. The Unemployment Insurance Act has proved even a more timely measure than was foreseen by most people while it was being put through. The Extension of Health Insurance Act, the Dyes Act, and the Act to give power to the Transport Minister, all dealt with subjects which at other times would have had a larger place in public attention. Two small bills which certainly deserve mention are that for establishing juvenile courts and the financial provision made to enable pensions for the blind to begin at the age of 50.

A considerable part of the time of the session was, of course, occupied with finance. Mr. Chamberlain has been generally condemned in business circles for maintaining and increasing the Excess Profits Duty, but although the most gloomy observations are made concerning the possible yield, as well as in reference to its effect on trade, the Chancellor of the Exchequer has continued to assert his confidence that one way or another his Budget of next year will give the estimated surplus. It remains to be seen who will prove to be right.

There is no doubt that the lack of co-ordination of Government business, to which reference in these notes has already been made, has had much to do with the misfortunes of Dr. Addison in his ambitious efforts to make the Ministry of Health thoroughly worthy of its purpose. The plain man in the street has been puzzled to know why housing and health, two of the biggest and most urgent administrative affairs, have fallen to the responsibility of a single Government department; but that is due rather to history than intention, and Dr. Addison, until he was recently relieved to some extent by Dr. Macnamara, who has taken up the labour problem in regard to building, has had to bear the full brunt of both affairs. Again, it is an open secret that in respect of the division of time for legislation Dr. Addison was handicapped by other Cabinet arrangements, and that is the reason why he made the error of producing an omnibus health bill, which united opposition without attracting sympathy. The position of that measure has been sufficiently dealt with in these notes, and it need only be said that the appointment of the committee to go into the whole question of hospital finance may be expected at any moment. One of the greatest regrets that must be felt by all interested in health legislation is that the Proprietary Medicines Bill, after having been given slow and considered passage to the Report stage in the House of Lords, failed to get time for progress in the Commons. The hope is that the work that has been done in this connexion will not be lost, but everyone knows that in the Commons this measure of reform will have to meet a good deal of criticism, due to the opposition of various interests.

No review of the session, however brief, can close without a reference to the dark shadow of unemployment. Mr. Lloyd George, in his speech on this subject just before the prorogation, was frank in saying that the measures which were being taken to relieve it could only be in the nature of palliatives. Recovery must depend largely on the restoration of peace conditions in the world and on the awakening of the people of this country to the fact that our trade can be recovered, even in those circumstances, only by increased industrial activity and by a more economic production. The wage does not matter; what does matter is the value given for it; and at the present time this, in many cases, is exceedingly unsatisfactory, and threatens to leave us behind in the world competition.

The Dentists Bill.

We summarize here the principal provisions of the Dentists Bill now before Parliament. The bill is concerned only with regulations to prevent unqualified practice; no extensions of treatment are contemplated.

Section I, which is to come into operation from one to two years after the commencement of the Act, provides that no person who is not a dentist registered under the Dentists Act of 1878 may "practise or hold himself out, whether directly or by implication, as practising, or as being prepared to practise, dentistry for fee or reward"; excluded from the application of this section are (1) dental practice by a qualified medical man; (2) extractions performed by a registered pharmaceutical chemist or registered chemist and druggist (provided that no local or general anaesthetic is used, that the case is urgent, and that no qualified medical practitioner or registered dentist is available); (3) minor dental work performed (in approved conditions and with the supervision of a registered dentist) in public dental services. Section II authorizes the establishment of a Dental Board with perpetual succession and a common seal; the first Board is to be composed of a chairman appointed by the Privy Council, three lay members appointed by the health authorities of England, Scotland, and Ireland respectively; three persons appointed by the General Council; and five persons who are, or have been, engaged in the practice of dentistry. Of the last-named group one must be a person who before the passing of this Act was not registered.

Section III establishes the right of admission to the Dentists' Register of certain persons (of good character, and having attained the age of 23) who are not at present qualified. These include (1) persons who for five years before the commencement of the Act engaged as their principal means of livelihood in the practice of dentistry in the British Isles, or who not less than one year before the commencement of the Act were admitted to the membership of the Incorporated Dental Society; (2) persons having for five years been principally occupied as dental mechanics, provided that within two years they pass the prescribed examination in dental mechanics, and within ten years thereafter they pass after the prescribed training) the prescribed examination in dentistry; (3) any person who within two years passes the prescribed examination in dentistry and whose principal means of livelihood at the commencement of the Act was the practice of dentistry, will be entitled to admission to the Register; (4) the same is true of a duly registered chemist who was in "substantial practice" as a dentist, and whose practice included "all usual dental operations," provided that he gives an undertaking that within five years from the date of his registration he will cease to carry on concurrently the occupations of chemist and dentist. In the case of ex-service men the Board may dispense with any of the requirements of this section if the public interest is not thereby prejudiced. Section IV lays down that a body corporate may carry on the business of dentistry if it carries on no other business, and if all the directors, managers, and operating staff thereof are registered dentists. A person who for five years has acted as director or manager of a body corporate engaged in dentistry is entitled, however, to be entered in a list kept by the Registrar especially for the purpose of this section—such a person shall be entitled to act as director or manager, but shall not by virtue of this registration be entitled to practise dentistry. Every body corporate carrying on the business of dentistry is required to transmit annually to the Registrar of the Board full descriptions of the directors, managers, and operators. Sections V to X define the powers and duties of a dental board, and authorize the transference thereto of certain powers and duties of the General Council under the Dentists Act of 1878 and the Medical Act of 1886; erasures from the Register are to be made by the General Council acting after consideration of the report of the Dental Board.

Medicines for Panel Patients.—Mr. Casey asked, on December 23rd, 1920, whether the Minister of Health was aware that Dr. Ritchie and Dr. Allott, of Howland Common, near Barnsley, had been informed by the Wakefield Insurance Committee that they were supplying or prescribing a quality of medicine to panel patients which was far too expensive; that Dr. Allott had been surcharged £15 for this alleged offence; that in consequence of the restrictions imposed, the doctors had notified persons on their panel that in future they would be unable to supply or prescribe the quality of medicine which, in their opinion, was necessary to many cases under their care; and what action he proposed to take to ensure that medical men were able properly to discharge their duties to panel patients by being permitted to prescribe and supply that which was essential to a speedy recovery irrespective of the cost of the drugs used. Dr. Addison replied that his attention had not been previously called to this case, and he was causing inquiry to be made. He could inform Mr. Casey, however, that medical benefit under the Insurance Acts included the provision of "proper and sufficient medicines," and no doctor could be surcharged in respect to prescribing unless the character or quantity of the drugs was "in excess of what may reasonably be necessary for the adequate treatment of his insured patients," and then only on the report of the Panel Committee consisting of doctors elected by the insurance practitioners of the area. Any local decision to surcharge a doctor was subject to appeal to the Ministry of Health.

England and Wales.

THE PEOPLE'S LEAGUE OF HEALTH.

As a result of a meeting held by the People's League of Health at the Cardiff City Hall on December 15th, under the chairmanship of the Lord Mayor, at which Sir Bruce Bruce-Porter, Dr. Eric Pritchard, Dr. Mary Scharlieb, and Dr. E. H. Stancomb, representing its medical council, were the speakers, a committee was formed to establish the work of the League in Wales. Among those organizing the Welsh Branch are: Dr. Edgar Collis, Talbot Professor of Preventive Medicine, Welsh National Medical School; Dr. Ewen J. Maclean, Chairman of the Cardiff Insurance Committee; and Mr. D. W. Evans, Director-General of King Edward VII Welsh National Memorial Association. The committee, in expressing its very high appreciation of the aims and objects of the League, considers the present moment singularly opportune for the furtherance of the campaign undertaken by the League, particularly in the direction of developing a public demand for health legislation.

MEDICAL TREATMENT OF LONDON SCHOOL CHILDREN.

The London County Council, on December 21st, agreed that for the year from April, 1921, to March, 1922, the allowances to hospital committees and school treatment centres in respect of the services of surgeons, doctors, and anaesthetists employed in the medical and dental treatment of school children under the Council's scheme, should be at the rate of £80 a year (instead of £70) for one half-day of two and a half hours' duration a week, and that the dentists' allowances be £65 a year (instead of £50 to £55) for the same time. The allowance to nursing associations in connexion with the treatment of minor ailments is to be at the rate of £175 a year (instead of £150) for the equivalent of the service of each full-time nurse, including her travelling expenses and the drugs and bandages and other necessities used in treatment. Six additional minor ailment centres and six additional half-time dental centres are to be set up. In the event of the necessity of calling in a local medical practitioner to see children at their homes as a result of treatment performed at the school treatment centres, the committees of the centres are to be responsible for the payment of doctors' fees, such fees to be reimbursed to the committees by the Council. The arrangements sanctioned for 1921-22 provide for the treatment of 32,620 cases of eye defects (as against 31,645 for the present year), 18,110 ear, nose and throat cases (against 15,845, the increase being due to the fact that some hospitals have refused to allow school children to attend their aural departments), 53,350 cases of minor ailments, 118,140 dental cases, and 2,628 ringworm cases, each representing some 10 to 15 per cent. increase upon the figures for the present year. The cost of all these arrangements is estimated at £90,715, an increase of £19,000 upon the cost for the present year, and of this increase £8,360 represents increased salaries of medical practitioners and dentists. The proposed payment compared with pre-war rates shows an increase of 60 per cent. in the salaries of doctors, and 50 to 60 per cent. in those of dentists.

Scotland.

HIGHLANDS AND ISLANDS MEDICAL SERVICES.

The following letter has been issued by the Scottish Board of Health to practitioners serving under the Highlands and Islands scheme:

"I am directed by the Board to refer to their Circular Letter of July 15th last and to inform you that, in view of the representation made to the Board by the Highlands and Islands Subcommittee of the British Medical Association, and after negotiation with the Treasury, it has been decided that the revised scale of fees set out in the letter referred to above should come into effect on January 1st, 1921.

"The following is the detailed statement of the fees that may be charged on and after the 1st proximo to the classes of patients defined in Article 3 of your Agreement with the Board:

"(a) In ordinary cases the fee shall not exceed 5s. for the first visit, and 3s. 6d. for each subsequent visit in the same illness.

"(b) In midwifery cases the maximum fee chargeable shall be £2 2s., including any subsequent visits that may be necessary; and

"(c) Fees as specified below may be charged for certain special services—namely:

Service.	Fee not to exceed— £ s. d.
1. Anaesthetic	2 2 0
2. " "	1 1 0
3. " "	1 1 0
4. " "	2 2 0

is or is not required)

5. Setting of fracture	1 1 0
6. Reduction of dislocation	1 1 0

"In all cases under head (c), except (2), the fee is intended to cover two subsequent visits."

Ireland.

ULSTER MEDICAL SOCIETY.

The second meeting of the session was held in the Medical Institute on November 18th, with the President, Dr. Thomas Houston, in the chair. Mr. Crymble read a paper on obstructions of the alimentary tract. The paper was illustrated by x-ray slides, from a selection of his own cases, thrown on the screen, and dealt chiefly with the more disputed aspects of abdominal affections, such as ileal stasis and mobile caecum.

The third meeting was held on December 2nd. Dr. W. J. Wilson, professor of hygiene and public health, Queen's University, Belfast, opened a discussion on present-day problems in public health; he dealt with the Ministry of Health Act, 1919, the interim report of the English Consultative Council on medical and allied services, and finally urged the Ulster practitioners, in view of the near approach of an Ulster parliament, to organize and see to it that any scheme for the prevention and treatment of disease should have their imprimatur. Dr. Williamson, chairman of the Public Health Committee, Professor R. J. Johnstone, Dr. H. W. Baillie, superintendent medical officer of health for Belfast, Dr. W. Burns, and Dr. Gardner Robb joined in the discussion. Mr. A. B. Mitchell moved, and Dr. Trimble, principal tuberculosis officer for Belfast, seconded, that medical inspection of children should be adopted. Dr. McKisack proposed, and Mr. A. Fullerton seconded, that a public health committee of the society be formed. Both these resolutions were passed unanimously.

The fourth meeting of the session was held on December 16th. Major J. A. Sinton, V.C., M.D., I.M.S., was elected an honorary fellow. Dr. St. George, Lisburn, read notes of an unusual case of arsenical poisoning. Mr. T. S. Kirk read notes on two rare tumours of the small intestine, and demonstrated sections of voluntary muscle showing the changes produced by confusion. A public health committee of seventeen members was elected.

Honour to Major J. A. Sinton, V.C.

The president of the society (Dr. Thomas Houston) and Miss Houston were at home to the fellows and members and their wives on December 18th, 1920, at the Medical Institute, Belfast. The event of the evening was the presentation of the certificate of honorary fellowship of the society to Major J. A. Sinton, V.C. The certificate is in the form of a triptych bound in Russian leather, ornamented by charming water colours of the Queen's University, the Royal Victoria Hospital, the Medical Institute, with reproductions of the Victoria Cross and the Russian Order of St. George, and the crests of the Indian Medical Service and of the Ulster Medical Society. It reads as follows:

"This is to certify that Brevet-Major John Alexander Sinton, V.C., M.D., D.P.H., Indian Medical Service, has been elected an Honorary Fellow of the Ulster Medical Society in appreciation of the conspicuous gallantry and devotion to duty which have earned for him the greatest distinction which a British soldier can obtain—the Victoria Cross for valour."

In presenting the certificate, Dr. Houston spoke of the graceful act of recognition of a doctor's courage by Sir William Whittla, who, when he built the Belfast Medical Institute, installed a beautiful window in memory of Dr. Smyth of Burtonport, co. Donegal, who lost his life during the typhus epidemic at Arranmore. He then referred to the specific act which gained Captain Sinton the V.C. at

Orak ruins in Mesopotamia in January, 1916. Major Sinton, in reply, thanked the Society for the honour bestowed on him, and spoke in glowing terms of the good work done by the civilian doctors temporarily in the army during the war.

Correspondence.

HOSPITAL STAFFS AND PAYING PATIENTS.

SIR.—Having been present at the conference of representatives of hospital staffs on December 21st, 1920, but unable, in spite of two attempts, to catch the eye of the chairman, I venture here to put forward that criticism of the Leicester motion which I was unable to utter in the hall. That motion seemed to me to spoil an otherwise excellent meeting. Voluntary payment by a patient of a fraction of the cost of his bare maintenance might, indeed, furnish argument for raising the salaries of those officers who are concerned with this department; never before has it been excuse for exaction of a fee by the honorary staff. The motion is, in fact, far too comprehensive, it was not adequately studied, it is calculated to raise acute discussion between the staff and their committee, and it deals a deadly blow to that voluntary system which the meeting pledged itself almost unanimously to support. I had previously forwarded to the Medical Secretary, and endeavoured in vain to move, an amendment as follows:

The honorary medical staffs of voluntary hospitals should treat without charge all hospital patients except (1) those on behalf of whom payment is made out of rates or State funds; and (2) those who, in the opinion of the Hospital Committee, are able to contribute a sum beyond that required for maintenance, and who are definitely accepted on that understanding as paying patients by that committee.

I claim for this amendment that it emphasizes the primary duty of an honorary staff, yet leaves them liberty to charge fees in certain cases which are clearly defined. Other classes might be added in great industrial centres, but, in absence of definition, there will be much scope for disagreement. At the Royal West Sussex Hospital we have, until this year, been solvent on the voluntary system, and hope to recover this position without special rate or State aid. The secretary asks every patient, or those responsible for him, to subscribe something, if he can afford it, according to his means. We do not yet take "paying patients," though we meditate doing so. The patients are not of that class, and the honorary staff have no desire to share in these voluntary maintenance fees. No doubt many other hospitals staffs are similarly minded, yet the Leicester motion would compel them to do this thing. Now the honorary character of the staffs of hospitals has hitherto been of the utmost assistance to their committees in raising voluntary subscriptions and donations; if these officers are to be paid for nearly every patient, clearly they must drop altogether the title "honorary," the consequences to the funds of hospitals will be quite disastrous, and the relation of the staff to the still "honorary" committee will be radically altered, and that entirely for the worse. It is idle to plead that this payment will be small, and to call it an "honorarium." The sum may or may not be small, experience has shown that such demands are apt to grow, but anyhow the principle involved is great, and it is certain that committees will not regard as "honoraria" sums extorted from them against their will as a commission on the funds which they receive.

Equally futile is the plea that this money may be devoted to various admirable purposes. Precisely the same excuse was advanced before appropriating fees due from county councils, yet what fraction of those fees has been assigned to such aims? I do not blame the staffs for pocketing the money duly earned, but it had been better to have put forward no other intention from the first. Such programmes will hardly gain credence a second time, when already speakers, hatched chickens of the staff. Yet, nothing for maintenance, junior members of the staff, who do toll on sums voluntarily subscribed, whether by patient or other party, for the former purpose? I would prefer to this the frank condemnation of the whole voluntary system

so ably urged by Dr. Peter Macdonald. The logic of his speech was admitted to be unquestionable, but his motion was rejected almost unanimously on the score of sentiment. Yet this same conference, shortly after, by a majority almost equally overwhelming, approved the motion of Leicester, crudely unsentimental, indeed mercenary as it was, on the score of logic!—I am, etc.,

Chichester, Dec. 25th, 1920.

G. C. GARRATT.

STASIS AND THE PREVENTION OF CANCER.

SIR.—In his presidential address to the Hunterian Society, reported in your issue of December 25th, 1920, Dr. Jordan refers, for the second time in three months in the columns of the medical press, to one of my "medical notes" which appeared recently in *St. Bartholomew's Hospital Journal*, and criticizes the note adversely. I refrained from replying upon the former occasion because Dr. Jordan placed me in an obvious dilemma: he spoke of me as a "well-known physician," but did not name me; nor does he name me now. But this second and fuller reference invites a brief rejoinder, and I make it in the assurance that Dr. Jordan is as much mistaken in his compliment as I believe him to be in his criticism.

Dr. Jordan says that I wrote "somewhat" as follows—the note was quite short, so that it puzzles me to understand why it should not be quoted exactly—"Cancer of the stomach comes generally 'out of the blue,' with no preceding history of gastric trouble." Although that is not what I said, it is certainly what I meant, and Dr. Jordan's "argument" by no means leads me to disavow it. His argument resolves itself into a simple statement that "radiological investigation reveals incontrovertible evidence of long-standing disorder." Then follows the recital of the case of "a lady," suffering from gastric cancer, who, on "careful questioning," admitted that "she had always been inclined to biliousness and constipation," and whose examination revealed "an enormously elongated pelvic colon," with "a caecum firmly impacted in the pelvis," and "filled with hard faecal masses firmly pressed into the wall of the rectum." The reference which such a state of things bears to the "preceding history of gastric trouble," which I said was not usually present in cases of gastric cancer, is not very clear.

When I wrote the note referred to I had in mind only my own experience. On reading Dr. Jordan's second somewhat scornful criticism I turned up the subject in some standard articles by really well-known authorities, to find (as is so often the case) that there was nothing at all original about my "note." I append the first four references which I came across. "It is not probable that previous disease has any influence whatever in the causation of (the) cancer" (Osler). "There is no evidence that chronic indigestion leads to cancer of the stomach" (Hale-White in *Albutt's System*). "It (that is, the cancer) frequently happens in those who have been hitherto quite healthy, and is not determined by any previous disease" (Frederick Taylor). "There is no definite information which leads us to suppose that gastritis leads to carcinoma; in fact, in a large proportion of cases the development of cancer is almost sudden in the midst of complete health" (Charles F. Martin in *Osler and McCrae's System*). I did not proceed further with my researches into the literature of the subject.—I am, etc.,

London, W., Dec. 25th, 1920.

THOMAS HORDER.

THE MINISTRY OF HEALTH AND THE PROFESSION.

SIR.—A section of the lay press is still continuing its attacks on the Ministry of Health by methods such as those on which you commented in your leading article of December 4th. In so far as this represents a genuine attack on the policy of the Government or the methods of the Minister the politicians concerned may be left to look after their own case. But it becomes evident that there is, as you hinted in your article, an attempt, influenced mainly by the tactics of party warfare, to undermine the position and machinery of the Ministry itself, and to discredit those of our own profession who are attached to it, and who, as civil servants, are precluded from making their own reply. In this respect the medical profession, as the custodian not merely of its own reputation and status but also of the interests of the community in relation to

health, is vitally concerned with the controversy, and it is to be hoped that the Association at least will hasten to make its influence felt.

The profession, with the Association as its mouthpiece, was largely instrumental in securing the establishment of the Ministry, in defining its objects, and in determining its powers and its character. We succeeded in impressing on the Government and on public opinion that the care of the health of the whole community was matter for a first class department of State, that in such a Ministry the status and power of the medical side was at least as important as that of the lay side, and that only by the complete, or almost complete, unification of the health administrative service could ultimate success be assured. The provisions of the Act establishing the Ministry, and the arrangements made in building up its organization and personnel, secured these things, as it seemed, on a firm foundation. In Sir Robert Morant and Sir George Newman, given equal status in the Ministry, the public had servants capable of formulating a health policy for the country which, though it might take decades to carry out, and however it might be modified by adequate professional and public discussion, would be such as could not fail to secure in the long run those national results for which the profession has long been striving and the enlightened public aspiring after. These results are now in real danger and even the basis is becoming insecure.

So to limit the powers of the Ministry and so to narrow its possibilities as to reduce it to the level of a secondary department; so to subordinate its medical side as to place it in a position of inferiority to the lay administration; so to bolster up the isolated medical work of other Ministries as to prevent the unification of national health administration under one central body, appear to be the objects aimed at. I judge, however, that if there is one thing which the medical profession will not tolerate, it is a recrudescence of the old situation in which medical and health matters languished under the Local Government Board and half a dozen other departments, where the representatives of the profession were for the most part the scullions of an unenlightened bureaucracy mainly interested in other concerns.

The health of the nation is a big enough affair for a first-class Ministry. It has been part of our policy that other matters should go, as some have already gone, from the Ministry of Health. It is part of our policy, too, that as soon as may be the medical side of the Poor Law administration shall be separated from the purely assistance side, that the health work of the Ministry of Pensions and of the Board of Education should be treated as integral parts of a unified health administration. In a Ministry of this type it would necessarily follow that public health would be one of the prime concerns of the nation, and that the medical profession would take its proper place in formulating, guiding, and carrying out a considered national health policy. Already the masterly memoranda and reports of Sir George Newman and the reports of the senior medical officers under him, have shown us in outline a policy which, though in many respects not immediately practical because of financial and other considerations, demonstrates a grasp of the relationship between medical education, preventive medicine, and curative medicine, between the work of the general practitioner as the base of all and that of the specialist, the research worker, and the administrator as his essential helpers, such as had never yet been placed before the profession and the public.

It is a calamity that at this early stage of its life the work of the Ministry, after the tragedy of the death of its great first secretary, should be hindered by the reluctance of health workers in other departments to associate themselves with it, should be prejudiced by the imperfect methods of the first Minister nullifying his excellent intentions, and should now be stultified by some of the important conclusions and suggestions of its medical side being blocked even from consideration by the action of lay administrators and political wire-pullers.

Again, may I urge the Association and the profession to exert all the pressure that they can towards supporting and completing the reforms on which the national health and well-being so absolutely depend?—I am, etc.,

H. B. BRACKENBURY.

Hornsey, Dec. 20th, 1920.

X RAYS FOR RINGWORM: THE RISK OF BALDNESS.

SIR,—The increasing number of claims against medical practitioners in respect of permanent alopecia following upon the treatment of ringworm of the scalp by x rays renders it desirable that those who may have occasion to use that method of treatment should warn the patient's parents of the possible after-effects.

The violent reaction which occasionally follows even minimum doses of x rays, in spite of all precautions, is otherwise apt to create a suspicion of overdosage or negligent technique, and give rise to claims which might have been avoided by a preliminary word of caution.—I am, etc.,

JAMES NEAL,

General Secretary, Medical Defence Union, Ltd.

4, Trafalgar Square, London, W.C. 2, Dec. 23rd, 1920.

THE RISKS AFTER OPERATION FOR TONSILS AND ADENOIDS IN OUTDOOR CLINICS.

SIR,—I was pleased to read Mr. E. Watson-Williams's article in the JOURNAL of December 11th and grateful to him for having brought forward this important subject.

All are agreed that the removal of tonsils and adenoids is an operation by no means devoid of post-operative sequelae, and yet for years the practice of their removal in the out-patient clinics has persisted. The lack of in-patient accommodation has been given as a reason for this unscientific and in many cases dangerous procedure, but do we really consider that this justifies the performance of the operation at all under such conditions?

I would go further and say that no hospital should undertake these cases unless it can provide some sort of after-care and treatment. Tonsils and adenoids are the causative factors in so many derangements of the ear, nose, throat, and of general development, that their removal under proper conditions is of primary importance.

No operation gives such speedy good results if performed thoroughly and in suitable surroundings, and *au contraire*, I might say no operation has been the cause of so much dispute because of inefficient removal and after-care.

Holding these views, and having repeatedly received just letters of complaint from parents, I have recently approached the board of management at Ancoats Hospital, with the result that a few beds have been set aside in an observation ward, so that these cases can be under observation for at least twenty-four hours.

I admit that twenty-four hours is little enough, but it at any rate allows the child to recover in a good measure from the effects of the anaesthetic and operation, permits of the observation and treatment of haemorrhage, and further, the child can return home during the daytime rather than in the night air.

In conclusion I would urge that hospitals undertaking these cases accept their responsibilities, and try to put this operation on a more scientific footing by providing efficient accommodation for temporary after-treatment or observation.—I am, etc.,

F. HOLT DIGGLE,

Honorary Aurist and Laryngologist to Ancoats Hospital, Manchester, and to the Manchester Board of Guardians.

December 20th, 1920.

VENEREAL DISEASE PROPHYLAXIS.

SIR,—Dr. H. B. Gladstone's letter on this subject in your issue of December 11th, 1920, entirely ignores the problem of the unchaste as it exists at the present moment. He relies on such phrases as "I do not doubt" and "it is probable" to carry conviction, and proposes to leave his so-called "vicious men" in ignorance of simple knowledge that would almost certainly prevent them contracting horrible diseases that not only may cause them much misery and pain, and perhaps an early death, but which they may also hand on to their future wives and children. I claim that such conduct is false to any ethical code.

I wonder whether Dr. Gladstone realizes the proportion of young men that he thus proposes to sacrifice to a cruel blind puritanical bias? Certainly half the adult unmarried male youth of this country, probably much more than half. The section of the community that would be included in Dr. Gladstone's "vicious" class would certainly contain the majority of those who preserved our country's freedom in many hard-fought fights by sea and land during the late

war—men who were ever willing to make the supreme sacrifice at the call of duty. To say that such a hero is "vicious" because he has occasionally been carried away by his virile and natural appetite is a monstrous calumny. It is only possible to pity the "morally strong" section of Dr. Gladstone's classification, whose "high moral tone" "you cannot fail to weaken" by teaching that disinfectants do really disinfect.

That "the moral fibre of the nation would be undermined" by a knowledge that the occurrence of venereal disease could be prevented in men by the immediate application of a solution of potassium permanganate 1 in 1,000, nobody but a very few fanatics can be so bold as to state as a serious proposition, whereas the converse, that the health of the nation would be greatly improved by such knowledge, can hardly fail to be admitted by those who have attempted an exhaustive study of the subject.

All will agree in the value of such societies as the Alliance of Honour for keeping well taught and well disciplined youths and maidens in the paths of sexual morality, and all will wish every success to similar organizations for educating the child and adolescent in self-control. But what about the incontinent *adult of to-day*? Is he to be permitted to contract and pass on an infection that can be prevented by immediate disinfection? Is scientific knowledge that can prevent to be withheld for a generation until purity leagues have had time to endeavour to prove results—results that "it is probable" will be negative?

The point is whether a possible but uncertain slight increase in clean sexual licence would be a worse thing for our country than the present terrible plague of venereal disease, which is increasing, and which, as one of the first of killing diseases, is filling our lunatic asylums, our blind schools, and our hospitals, and is accountable for more distress of mind than all other diseases put together.

The note published by the Medical Women's Federation in your issue of December 18th, 1920, appears to be entirely uncalled-for, as I believe that every member of the Society for the Prevention of Venereal Disease will agree with their headings "(a), (b), (c), (d)"; but as no one previous to this note, so far as I am aware, has ever raised such an ugly bogey, why raise it only to knock it down with so much energy?

The "directions for women" are "issued only by request" by the Society for the Prevention of Venereal Disease at my discretion as the honorary secretary, and are not issued broadcast; they are intended for the use of prostitutes, and for distribution by medical women and health workers in touch with prostitutes, either professional or amateur.

The policy of the Society for the Prevention of Venereal Disease is clearly stated in the first affirmation of our letter in your issue of December 4th, 1920, emphasizing "the efficacy of immediate self-disinfection in the male as a prevention against venereal infection and the possibility of almost eradicating these diseases by this means."—I am, etc.,

London, W., Dec. 22th, 1920.

H. WANSEY BAYLY.

SIR,—As a medical woman and a member of the executive committee of the Society for the Prevention of Venereal Disease, I wish to protest most strongly against the communication by the Medical Women's Federation which appears in your issue of December 18th, 1920. It is calculated to give an utterly wrong impression of the aims and methods of the Society for the Prevention of Venereal Disease; only entire ignorance of the policy of the society can explain or excuse this extraordinary communication.

It is regrettable that a body of educated women should allow themselves to be involved in so serious a controversy without first verifying the accuracy of their information.

It is true that the "note" issued by the Federation does not say in so many words that the paragraphs marked "(a), (b), (c), (d)" are criticisms of the instructions issued by the Society for the Prevention of Venereal Disease, but there is no other interpretation possible. On behalf of the Society I repudiate the suggestions put forward in these paragraphs. The references to instructing young boys and girls even before puberty, and those that refer to teaching women—not even excepting a bride—to regard their husbands as possible sources of infection, are alto-

gether unjustifiable and revolting. The Society has not issued any instructions capable of such interpretation, nor does it propose to do so.

The question of contraceptives does not concern us here, since the information on immediate self-disinfection given by the Society is for the use of men, and for those women who, by reason of their mode of life, tend to become a source of great danger to the community. Such women do not, as a rule, become mothers, nor is it desirable that they should, since their offspring are not likely to become good citizens, or to add to the health of the nation.—I am, etc.,

London, W., Dec. 21st, 1920.

J. LORIMER HAWTHORNE.

MUSCLE RE-EDUCATION IN INFANTILE PARALYSIS.

SIR,—From the controversy in the BRITISH MEDICAL JOURNAL under the above heading one gets, I think, a good example of how easily discoveries are lost sight of and after some time rediscovered. Several writers have shown beyond doubt—particularly Dr. Cyriax—that the principles and practice of muscle re-education in infantile paralysis is no new discovery born by the war, as proposed by Dr. Mackay, but has been known and practised by the Swedish school for many years. This may be put on the credit side for the Swedish school, and needs no further comment, except that one would have wished for the publication of their principles to have been kept abreast with modern investigations and findings.

When, however, Dr. Cyriax, in your issue of December 11th, states that "splinting is not essential in the treatment of infantile paralysis," and "that during the last seventy years the Swedish school have treated this disease without splinting," I for one, as a pupil of that school, must emphatically protest, as I entirely disagree with that view. Further, I do not believe Dr. Cyriax is voicing the opinion of the main bulk of the Swedish school when he makes that statement, but is rather giving the opinion of a minority with extreme views on the subject. If he was, I think it would be most regrettable, as it would show that in spite of rational and advanced views on one hand, they would have shut their eyes to other therapeutic measures of equal importance and ignored the teaching of sound physiological principles which investigation and experience have shown beyond doubt to be correct. Moreover, it is indeed difficult to understand this aversion in some quarters to splinting in bad cases, as the physiological reason for splinting is closely allied to the guiding principle in re-education of paralysed muscles. Take, for example, the case of drop-foot from paralysis of the anterior tibial group of muscles. On the one hand the splint, by bringing about what might be called a passive shortening of the dorsiflexors and stretching of the antagonists, mechanically keeps the foot in a position the active maintenance of which will ultimately constitute complete recovery of the now paralysed muscles. On the other hand, the same position is used as a starting-point for re-educative movements. With this the Swedish school, as voiced by Dr. Cyriax, seem to agree. Now, however, comes the difference. The modern surgeon, who generally favours manipulative treatment, including re-educative movements, removes the splint for that purpose, being careful, however, not to permit, even for a short while during treatment, the foot to hang limp, in order to prevent any overstretching of paralysed muscles. Dr. Cyriax in using the same treatment, but by applying no splint in the interval, permits the foot to hang limp all day and all night, and only during treatment once or twice a day brings it up to the position he hopes the muscles themselves will be able to maintain one day.

If "the rule of the Swedish school has always been to place the affected limb in that position from which the greatest sign of muscular activity were obtainable," why, may it be asked, is not this position artificially maintained during the twenty-three hours of the twenty-four when the limb is left to itself and no treatment is being given? The individual muscle fibre, just recovering its tone, must surely find a great relief in being spared the irritating influence of being overstretched. Why should not this relief be given continuously, instead of only for a short while during the day? If good results have been obtained without splints, one can only infer that those cases were

The decision is interesting, because at the inquest which had been held on the deceased the coroner found a verdict of accidental death. It is not to be supposed, however, that the defence of "suicide" will always succeed in answer to a claim under the Act. In another case of recent date the Court of Appeal decided that where a workman commits suicide by reason of insanity resulting from an accident arising out of and in the course of his employment, his dependants are entitled to compensation if the suicide was a result of the accident and *not* a result of the brooding over the injury received. In that case a medical specialist had expressed the opinion that he was suffering from insanity. In his opinion the accident had given the man a shock, and the shock and suffering had resulted in melancholia, which had been the first stage of insanity. In his view the melancholia, resulting from the accident, left no doubt as to the cause of insanity.

Medical News.

DR. C. OWEN FOWLER, president of the Surrey Branch of the British Medical Association, has been appointed a magistrate for the Borough of Croydon.

DR. A. G. NEWELL of Harringay, a vice-president of the Medico-Political Union and chairman of its Finance Committee and vice-chairman of its Executive Committee, informs us that he has resigned from that Union, owing to his opposition to certain lines of policy.

DR. T. R. LLEWELLYN, on the occasion of his leaving Penygraig, near Pontypridd, to take up an appointment of regional officer under the Ministry of Health, has been presented by his friends with gifts to the value of £400, including a medical dressing case, and a diamond wristlet watch to Mrs. Llewellyn.

AMONG the Friday evening discourses to be given at the Royal Institution of Great Britain, 21, Albemarle Street, W.1, is one on February 4th at 9 p.m., by Professor A. D. Waller, M.D., F.R.S., on the electrical expression of human emotion. The lecture programme includes a course of four lectures to be delivered on February 22nd, March 1st, 8th, and 15th by Professor Arthur Keith, M.D., F.R.S., on Darwin's theory of man's origin in the light of present-day evidence.

DR. THOMAS FAWCITT of Oldham was recently entertained by his medical colleagues at dinner in commemoration of his retirement after fifty years' practice. The function was arranged under the auspices of the Oldham Medical Society.

DR. FRANK HEWKLEY, vice-president of the League of Mercy, has been awarded the Order of Mercy.

DR. JOHN MCGIBBON, lecturer in midwifery and gynaecology in the Edinburgh Extramural School, has been appointed professor of midwifery in the University of Johannesburg, South Africa.

THE annual general meeting of the Medical Officers of Schools Association was held at 2, Savoy Hill, Victoria Embankment, W.C.2, on December 17th, 1920. Mr. R. C. Elmslie was elected president, and thanks were accorded to Dr. James Kerr, the retiring president. It was agreed to continue publication of the journal, *School Hygiene*, and Drs. James Kerr and C. W. Hunt were elected editors.

THE Aldred Lecture before the Royal Society of Arts on Wednesday, January 12th, at 8 p.m., will be given by Dr. C. S. Myers, F.R.S., Director of the Psychological Laboratory, and Lecturer in Experimental Psychology, University of Cambridge. The subject is "Industrial Fatigue."

THE officers of the 29th General Hospital, stationed at Salonica during the war, held their second annual Reunion dinner at the Queen's Hotel, Manchester, on December 11th, 1920. Lieut.-Colonel S. H. Withers, C.M.G., R.A.M.C.(R.), presiding. There was a large and enthusiastic company present, including Colonel Sir Wm. Thorburn, K.B.E., C.B., C.M.G., Colonel R. J. Kelly, C.B., Lieut.-Colonel W. Thompson, Lieut.-Colonel H. T. Fairbank, O.B.E., D.S.O., Major J. Arnold Jones, O.B.E., Major A. Corsar Sturrock, Major Wm. Stewart, Major Webster and Captain A. Percy Groves.

ON the occasion of his eighty-fourth birthday Dr. W. W. Keen will be entertained at dinner and presented with his bust by a number of medical, scientific, and civic organizations, and by friends in Philadelphia and other cities.

As will be seen by an advertisement elsewhere, the Indian Government is inviting applications for two Tata professorships at the School and Hospital of Tropical Medicine about to be established in Bombay. The selection of the candidates for the two chairs—the first in clinical medicine and therapy, and the second in protozoology—has been placed by the Indian Government in the hands of the Tropical Diseases Committee of the Royal Society. The appointments are whole-time, and are made in the first instance for five years, but may be extended by the Indian Government, on the recommendation of the governing body of the school. A condition with regard to salary is rather unusual; the offer is of 1,500 to 1,000 rupees a month, according to the scientific standing of the candidate. There is no pension. If the appointment is renewed the incumbent will be entitled to furlough for six months out of India on full pay, and so thereafter for each period of five years. The incumbent may also be able to obtain study leave on furlough pay for six months out of India.

A THREE months' course of lectures and demonstrations in hospital administration for the diploma in public health will be given by Dr. R. M. Bruce, medical superintendent, at the Western Hospital, Seagrave Road, Fulham, on Tuesdays and Fridays, at 5 p.m., beginning on Tuesday, January 4th. The fee for the course is £3 3s., and payment should be made beforehand to the Metropolitan Asylums Board.

ON Saturday, December 11th, 1920, in the Hotel Majestic, the annual oration of the Harrogate Medical Society was delivered by Sir Berkeley Moynihan, K.C.M.G., C.B., on the subject of gastric ulcer. Many illustrative lantern slides of radiographs were shown, some of which were unique. The President, Mr. Herbert Frankling, C.B.E., and over 80 members of the Society and other guests, including members of the nursing profession, were present.

DR. R. L. GUTHRIE, O.B.E., has been appointed His Majesty's coroner for the Eastern District of the County of London.

LAST summer a request was received from the Council of the National Institute for the Blind for permission to publish in Braille, for the use of blind students of massage, certain articles appearing in the *BRITISH MEDICAL JOURNAL*. In making the application, which was readily granted, the aim of the Council of the Institute was to help its students to have as far as possible the same opportunities as sighted persons for keeping in touch with subjects likely to be of benefit to them in their work as masseurs. Mr. J. Lloyd Johnstone, M.R.C.S., librarian of the Institute, now informs us that some half-dozen papers have been reproduced in Braille and are kept for use in the library of the institute. Among these are Dr. Wilfred Harris's lecture on chronic paroxysmal trigeminal neuralgia, Dr. R. G. Abercrombie's note on physiopathic paralysis of the hand, and Dr. Charles Mackay's paper on the place of muscle re-education in the treatment of anterior poliomyelitis.

Letters, Notes, and Answers.

As, owing to printing difficulties, the *JOURNAL* must be sent to press earlier than hitherto, it is essential that communications intended for the current issue should be received by the first post on Tuesday, and lengthy documents on Monday.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *BRITISH MEDICAL JOURNAL* alone unless the contrary be stated.

CORRESPONDENTS who wish notice to be taken of their communications should authenticate them with their names—of course not necessarily for publication.

AUTHORS desiring reprints of their articles published in the *BRITISH MEDICAL JOURNAL* are requested to communicate with the Office, 423, Strand, W.C.2, on receipt of proof.

In order to avoid delay, it is particularly requested that ALL letters on the editorial business of the *JOURNAL* be addressed to the Editor at the Office of the *JOURNAL*.

THE postal address of the *BRITISH MEDICAL ASSOCIATION* and *BRITISH MEDICAL JOURNAL* is 423, Strand, London, W.C.2. The telegraphic addresses are:

1. EDITOR of the *BRITISH MEDICAL JOURNAL*, *Aitiology*, Westrand, London; telephone, 2630, Gerrard.
2. FINANCIAL SECRETARY and BUSINESS MANAGER (Advertisements, etc.), *Articulate*, Westrand, London; telephone, 2630, Gerrard.
3. MEDICAL SECRETARY, *Medisecra*, Westrand, London; telephone, 2630, Gerrard. The address of the Irish Office of the *British Medical Association* is 16, South Frederick Street, Dublin (telegrams: *Bactina*, Dublin; telephone, 437, Dublin), and of the Scottish Office, 6, Rutland Square, Edinburgh (telegrams: *Associate*, Edinburgh; telephone, 4361, Central).

QUERIES AND ANSWERS.

HIGH MYOPIA.

"OCULUS" has a case of a boy, aged 10½ years, with a large patch of old choroidal atrophy in the macular region of the right eye and myopia of 10 D in the left. Visual acuity amounts to R. 5; not improved by glasses, and to L. 5; improved to 2; by -10 D sph. The myopia in the left eye is evidently increasing. In view of the risk of increase of myopia, separation of the retina, etc., in the left eye, how is the boy's education to be continued? Would such a case be received into a school for the blind, or are there any special schools for myopes to which he could be sent? "Oculus" asks for information with regard to schools or classes for myopes suitable for such a case.

The youth of this child, the serious defect of the eyes amounting to loss of the central vision of the right and poor vision in the left—make it dangerous for education to be carried on at an ordinary school. There are many classes for

children with high myopia now established in connexion with the elementary school system, and working after the model inaugurated in London. This scheme of education can be secured in some public schools by favour of the head masters. Mr. Bishop Harman, who has oversight of the London blind schools and myope classes, informs us that this boy would not be admitted to a myope class, but entered for a blind school. His vision would be too bad to do the work of the myope class, and the grave risk of further deterioration of vision makes it necessary that the boy should learn Braille at a time when he can do it with the greatest ease; so that, should the worst be realized, he would have command of the recognized means of communication amongst the blind, and of a full literature.

INTELLIGENCE TEST.

"J. A. M."—We understand that the most satisfactory apparatus for carrying out tests for mental deficiency is the test material for the measurement of intelligence devised by Mr. Ferman, Professor of Education, Leland Stanford Junior University. The material can be obtained from Messrs. H. K. Lewis and Co., Ltd., 136, Gower Street, W.C.1, price 3s. 6d. net.

INCOME TAX.

"A. H. G." inquires if the cost of a six months' post-graduate course in radiology can be treated as a professional expense in calculating the profits of his general practice including radiology.

"*." We think not. The expense seems to represent outlay in improving his mental equipment, and is analogous to the expense of purchasing additional machinery or instruments.

"T. N. C." inquires whether the cost of replacement of a motor car is to be measured according to the original cost of the car displaced as a maximum.

"*." We have dealt with this point before, and can only say here that the official evidence put before the Royal Commission by the Board of Inland Revenue justifies, in our opinion, a claim to the full cost of the replacement, provided that the car purchased does not cost more than the old car would have done in present circumstances.

"H. E. B." inquires as to the inclusion of certain income in the Schedule D return.

"*." He can include the "regular salary as district medical officer" but not, as we think, the "pension for disturbance out of former office under the guardians"; in the latter case no expenses are chargeable against the income and there seems to be no reason, therefore, for departing from the strict legal procedure.

"A. M." asks if a medical practitioner can deduct (a) £500 spent in purchasing a "panel," and (b) the cost of purchasing a small car.

"*." No; in both cases the cost represents an outlay of capital sunk by our correspondent in the purchase of a practice and equipment. The cost of replacing the car will normally be deductible as an expense of maintenance.

LETTERS, NOTES, ETC.

TREATMENT OF ERYSIPELAS.

DR. E. T. LARKAM (Birmingham) writes: Amongst the many fairly recent suggestions for the treatment of cutaneous erysipelas an old effective method by means of the local application of the strong solution of perchloride of iron (lig. ferri perchlor. fortis) has not, to my knowledge, been mentioned. In 1893, when a house-surgeon, I had to treat a virulent case following amputation of a toe; in four days the erysipelas had spread just above the knee, in spite of the application of ichthyol, painting a broad band of liquor iodi fortis above the upper limit of the disease, and the internal administration of large doses of tincture of perchloride of iron. I thoroughly painted the limb with the strong iron solution, continuing the painting two inches above the upper limit of the disease on healthy skin; at the same time I applied lint soaked in the iron solution and covered the limb with cotton-wool. This dressing was carried out twice daily. The erysipelas spread but slowly during the next forty-eight hours, and in three days became totally arrested. I have had many such cases since, including the so-called idiopathic facial variety, and have invariably used this remedy, with unflinching success.

POSTURE IN DEFAECATION.

"R. B. G." writes, with reference to Dr. D. de V. Hugo's communication (December 11th, 1920, p. 923), that he remembers an address given by Professor Chiene on "Movement in life," wherein he emphasized the benefit of what he called the "cuddy-hunker" position in defaecation as witnessed by him on the wayside in South Africa, with resulting large well-formed stools, as compared with the broken-up and

ill-formed faeces of those who adopted the ordinary sitting posture on the modern closet. His advice was—"defaecate slowly" and "micturate slowly."

"*." We are glad to say that Dr. Hugo was in error and that Emeritus Professor John Chiene, C.B., is still happily living in retirement in the Midlands.

A TEAPOT STIRRER.

DR. LACHLAN GRANT (Ballachulish) has designed a simple means for obtaining a better and quicker infusion of tea in an ordinary teapot. This consists of an attachment of aluminium fixed to the inside of the cover of the teapot. By turning the knob of the lid the contents are agitated and the infusion is hastened. Thus the lid need not be lifted in order to stir up the contents with a spoon, nor need the teapot be waved about as some old-fashioned ladies used to do. The "stirrer" can be attached to teapots made of earthenware, porcelain, or metal. Teapots so fitted are, we understand, manufactured by Messrs. Gibson and Sons, Limited, Albany Potteries, Burslem, Stoke-on-Trent.

RABIES IN SOUTHERN INDIA.

THE annual report of the Director of the Pasteur Institute of Southern India, Coonoor, shows a further increase of 347 in the number of patients annually undergoing treatment for rabies; and has been purchased for the erection of two new wards for indigent and one for paying patients. In 1920, six patients died from rabies; eight died less than a month after the completion of treatment, and twenty-four more than fifteen days after the completion of treatment. The last are classed as failures, giving a rate of 0.75 per cent. The patients comprised 3,000 Asiatics, 100 Europeans, and 75 Eurasians.

THE DECLINE OF LATINITY IN FRANCE.

WE can only speculate as to the psychological reason that led the French to frenchify scientific terminology, more particularly in anatomy and pathology. Molière, it is true, brought medical dog latin into disrepute by his satire in *Le malade imaginaire*, but the change into the vernacular took place so long after Molière poked fun at the mediæval practitioner that they do not seem to stand in the relation of cause and effect. The explanation would no doubt be that it is much simpler to deal with French names than Latin, but it may be doubted whether the change is really of the nature of a simplification. It seems simpler to speak of the pudic nerve than the shameful nerve, the gluteal muscles than the buttock muscles (*muscles fessiers*). The practice of naming operations and diseases after their supposed inventors is carried to an extreme in France, and such inventors are invariably, or almost invariably, French. The only exceptions we can recall are Bright's disease, Addison's disease, and, occasionally, Barlow's disease, but for the last named there is a Frenchman who has a reversionary interest. So far as we are aware, no other country has pushed Chauvinism to this degree in matters scientific, and we venture to hope that Latin will preserve its ascendancy. Owing to differences of pronunciation—in which we English are the greatest sinners—even Latin ceases to be a uniform spoken language, but it is universally understood when written. Re it remarked, however, that in France Latin is no longer compulsory, so that some present-day students, medical and pharmaceutical, are unable to tackle even a simple prescription in that classical language.

CORRECTION.

THE name of Mr. G. E. Elkington was incorrectly printed in the list of successful candidates for the diploma of F.R.C.S. Eng., published in our issue of December 18th, p. 956.

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 29, 30, 32, 33, and 34 of our advertisement columns, and advertisements as to partnerships, assistantships, and locum tenencies at pages 31 and 32.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Six lines and under ...	0	9	0
Each additional line...	0	1	6
Whole single column (three columns to page) 7 10 0	7	10	0
Half single column ...	3	15	0
Half page ...	10	0	0
Whole page ...	20	0	0

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 422, Strand, London, not later than the first post on Tuesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive post-
vante letters addressed either in initials or numbers.

EPITOME OF CURRENT MEDICAL LITERATURE.

MEDICINE.

1. The Dietetics of Diabetes.

FILIPPINI (*N. Morgagni*, September 25th, 1920, and *Il Politecnico*, July 3rd, 1920) describes the fasting treatment of Allen. The disappearance of sugar from the urine under this treatment has no relation to the amount originally present, but depends more on the duration of the disease and on the patient's age. When the sugar has disappeared the tolerance for carbohydrates has to be determined by starting with green vegetables containing 5 per cent. of carbohydrates and going on to richer vegetables. The amount of such vegetables seldom reaches 3 grams per kilogram of weight. When the urine has remained free from sugar for two days, the tolerance for albuminoids must be determined, the amount of fish, egg albumen, etc., is increased until 1 gram per kilogram of weight is reached. Subsequently fat may be given. Apart from the fasting treatment, weekly fast days are very useful for diabetics; thin subjects stand the fasting treatment better than fat. One objection to the Allen treatment is the very restricted diet, which tends to inanition. Other diets allow more food, and the various vegetarian régimes have the advantage of making the patient (who is often ravenous) more satisfied, the bulk of food is much greater, and such a diet tends also to stimulate peristalsis. Oatmeal diet, used by some, is apt to cause oedema. Carbohydrate diets favour the accumulation of water, of carbohydrates and albumin, and lessen acidosis. Probably glycosuria is the only thing common to many so called cases of diabetes, so that the individual metabolic defects of a series of cases may be widely different; hence the value of different diets. Whatever treatment is adopted, there is no doubt it should be started early, should entail a reduction in diet, should include days of fasting, and should recognize the utility of a vegetarian diet.

2. The Blood Pressure of Aviators

L. GRANDJEAN (*Ugeskrift for Læger*, August 26th, 1920), using Pachon's sphygmometric oscilometer, has carried out blood pressure measurements on 28 aviators at an aerodrome in Denmark. The measurements were made immediately before and after flights, and the maximum blood pressure was found to be between 12 and 16 before flight and the minimum pressure between 8 and 10. Only in one case was the maximum pressure 17 and the minimum 11. In this connexion the author notes that in other countries the minimum pressure of candidates for aviation is kept within the bounds of 8 and 10. The measurements after flight bore no constant relation to measurements before flight: in 9 cases the maximum pressure had fallen, in 5 cases it had not altered, and in 14 cases it had risen. The effects of flight on the minimum pressure were more uniform. In 18 cases it had risen, in 8 cases it had remained unaltered, and only in 2 cases had it fallen. The author has compared these figures with measurements of the blood pressure taken after gymnastic exercises, carried out just before flight. These exercises reduced the minimum pressure in 11 cases and failed to affect it in 14. Only in 3 cases did they increase the minimum pressure. The author concludes by suggesting that the explanation of many obscure aviation fatalities is to be found in arterial hypertension or vasomotor hyperemia, giving rise to giddiness, somnolence, and other dangerous symptoms.

3. Ocular Symptoms in Lethargic Encephalitis

DAVINO (*Riv. Sci. Med. di Endocrini*, August 15th, 1920) made an ophthalmological examination of six cases of lethargic encephalitis with the following results. The optic nerve did not show any changes. The external or internal ocular muscles, and so sometimes both, were affected. As a rule there was only a slight paresis, and in only one case was there a true paralysis, the oculomotor nerve was the one most frequently affected. In no case did the lesion involve the whole nerve as in syphilis. The ocular movements were affected in two respects—namely, in the nature of their extent and in a diminution of their rapidity. No signs of affection of the sympathetic were found, even in three patients who showed vasomotor muscles of the face.

Blindness and Oxycephaly.

RATIE (*Journ. de méd. et de chir. prat.*, August 10th, 1920) states that the chief interest of oxycephaly is that it may be accompanied by ocular disturbances such as exophthalmos, nystagmus, strabismus, and especially optic neuritis. Operations which do away with endocranial hypertension, such as lumbar puncture, ventricular puncture, or trepanning, stop the progress of the neuritis, and if employed at the outset may prevent blindness. X rays often show at the base of the skull or in the sella turcica a deformity which causes a compression and deviation of the optic nerves. In addition to ocular symptoms oxycephaly often gives rise to headache, convulsions, vertigo, and olfactory disturbances. Idiocy and congenital dementia have been observed. The intelligence, however, is usually normal and even above the average, as in the cases of Paracelsus, Humboldt, Walter Scott, and Meckel. Blindness may occur without affection of the intelligence.

5. An Unusual Case of Mercuric Chloride Poisoning.

MCPECK (*Journ. Amer. Med. Assoc.*, September 4th, 1920) records the sequelae of the contraceptive use of a hastily prepared douche by which an almost entirely undissolved tablet of 7½ grains of mercuric chloride became lodged in the posterior vaginal fornix. Three hours afterwards the patient suffered from severe abdominal pain, nausea, vomiting, and syncope attacks. Within thirty six hours a black line appeared on the upper and lower gums, subsequently the teeth became loose, there was marked salivation, and the nasal mucosa sloughed. Three days after the douche was taken there was complete suppression of urine; four months afterwards the urine still contained albumin and casts. A large ulcer on the posterior portion of the cervix persisted for six weeks.

6. Adenitis in Herpes Zoster.

ACCORDING to RAMOND and LEBEL (*Bull. et Mem. Soc. Méd. des Hop. de Paris*, August 5th, 1920) the primary adenitis of herpes zoster, which was first described by Barthélemy in 1892, presents the following characters: Its position is determined by the topography of the eruption, the axillary glands being affected in zoster of the upper limb and of the supra umbilical portion of the trunk (this includes intercostal zoster), the inguinal glands in abdominal zoster and zoster of the lower limbs, the pre auricular glands in ophthalmic zoster, the suboccipital in occipito cervical zoster, the submaxillary and subhyoid in superior or inferior maxillary zoster, and the superficial cervical in zoster of the neck. Like the eruption, the adenitis is unilateral. It appears at an early date, before any ulceration of the skin. Spontaneous resolution always takes place, and suppuration and chronic adenitis are unknown. Secondary adenitis in zoster is not a symptom, like primary adenitis, but a complication due to infection of the vesicles. It is relatively rare, is always a late event, and shows a tendency to suppurate. Uncomplicated herpes simplex and zosteriform eruptions are not accompanied by adenitis.

7. Early Diagnosis of Pulmonary Tuberculosis

BOERI (*Riv. Med.*, August 14th, 1920) during the war saw many cases of phthisis among soldiers and prisoners of war, and contributes certain notes on the subject. He believes that sufficient attention is not paid to prophylaxis, especially with reference to careful watching of those predisposed. To recognize these subjects, in addition to the usual criteria he draws attention to the frequent existence in these people of the vertical heart and floating tenth rib; they usually suffer from neuro muscular asthma, dyspepsia, etc. Examination of the respiratory capacity is useful, a chest which, from the anatomical point of view, appears sound may be functionally feeble and may exhibit limited respiratory capacity (the reverse also holds good). Many of these predisposed subjects have a history of chest weakness. As additional helps towards the early physical diagnosis of phthisis, the author draws attention to lack of development of the edge of the trapezius and sternomastoid on the diseased side, together with hypertrophy on the sound side. Direct percussion of the clavicle should not be omitted. The exclusion of tubercle, when the signs seem to point to it, is sometimes difficult. Influenza often gives apical signs which are very suggestive, but change more rapidly than in tubercle. In all

enormously dilated, the ductus arteriosus was as large as the aorta, and there was free communication between the ventricles. Flamma concludes that hydrops foetus universalis is due to a single mechanical cause—namely, obstruction to the circulation, the obstruction being due to malformation or tumours in the principal foetal organs and their appendages or to naked eye and microscopical lesions in these organs caused by toxins transmitted from the mother. All cases of foetal dropsy are associated with hydramnios, as in Flamma's case, and pregnancy should be interrupted at an early stage.

27. Vaginal Preparation for Extended Hysterectomy.

In consequence of the deterioration of the quality of benzine during the war, ELGART (*Casopis lékařů českých*, 1919, 35, quoted in the *Zentralbl. f. Gynäk.*, September 11th, 1920) was unable to perform cauterization in extended abdominal hysterectomy. In cases where the portio vaginalis was unaffected he occluded it by stitch and suture. Where this region was the seat of a growth he split the vagina into two halves by means of a circular incision. The upper half was prepared in a sleeve-like fashion, and was made to cover the cervix during the removal of the extirpated parts. This method is stated to have the advantage that the preliminary vaginal operation will disclose any existing extension of the growth to the bladder; the impossibility of abdominal extirpation is thus recognized, and coeliotomy is not undertaken.

28. Vaginal and Cutaneous Diphtheria.

LINDEERTZ (*Med. Klinik*, 1920, No. 6) records the case of a child of 5, who, shortly after the death of two sisters from diphtheria, was suddenly seized with pains on urination. The neck and nose were normal, but there were reddening and swelling of the vulva and vagina, and an impetiginous condition of the mons veneris; later, infiltrated, ulcerated swellings were found in the coccygeal and gluteal regions, and the vaginal inflammation became definitely membranous. The inguinal glands were swollen and painful; diphtheria bacilli were found in the cutaneous and genital lesions. During convalescence paresis of the palate and of both abducent and both oculo-motor nerves was noticed, together with urinary and faecal incontinence.

29. Vaginal Cyst probably of Wolffian Origin.

THIÉRY and LAZARIDES (*Bull. et Mém. Soc. Anat. de Paris*, July, 1920) report the case of a woman, aged 26, who ten days after confinement began to suffer from abdominal pain, most marked in the right iliac fossa. Vaginal examination showed a rounded painless swelling, the size of a hen's egg, attached by a broad pedicle to the vaginal wall close to the cervix. The cyst, which contained a thick yellow fluid, was extirpated under general anaesthesia, and was found to be lined with cylindrical epithelium. The wall, which was formed of connective tissue and muscle, was infiltrated with a few polymorphonuclears and numerous mast cells, indicating a certain degree of subacute inflammation.

30. Syphiloma Vulvae.

STEIN (*Surg., Gynec., and Obstet.*, September, 1920) records two cases of this condition occurring in coloured women aged 20 and 22 respectively; the Wassermann reaction was positive in both. The author believes that the names *esthiomène* and *lupus vulvae* should no longer be employed, and that *syphiloma vulvae* correctly designates the disease as a manifestation of tertiary lues. In view of the long-standing character of the specific infection in the majority of cases, it is not to be expected, it is said, that the Wassermann test should be invariably positive. The treatment should consist of operative removal of all tumours, hypertrophied tissues and ulcers, followed at the same session by cauterization, and combined with intensive antisyphilitic medication.

31. Pedicular Torsion in Ovarian Cysts.

KIOLBASSA (*Zentralbl. f. Gynäk.*, September 11th, 1920) records 24 cases of pedicular torsion among 328 cases of ovarian cyst (7 per cent.). The condition was most frequent between the ages of 40 and 43, and was more common among multiparae. No death occurred among this series of cases, which were treated by immediate laparotomy and removal of a tumour after application of several ligatures to the pedicle. The condition appeared to be equally common on both sides, and was encountered four times more frequently in benign than in malignant cysts.

PATHOLOGY.

32. Pneumococci in Throats of Normal Persons.

A STUDY was made by MEYER (*Journ. Amer. Med. Assoc.*, November 6th, 1920) on 100 normal individuals of varying ages, in whom no history of contact with an acute or recent case of lobar pneumonia could be obtained. Pneumococci were found in twenty-one instances; Types I and II were not found in any case. Type III was isolated once; Type III occurred in three instances, and Type IV in seventeen. The organism identified as Type III by the precipitin method was soluble in bile, but did not ferment inulin. Of the seventeen strains of pneumococcus Type IV, eight were apparently more readily soluble in bile than the remaining nine. As the diagnosis of this group largely depends on the bile reaction, the bile test was repeated. All seventeen strains were found bile-soluble, but the results did not correspond closely with those obtained when the organisms were first isolated. Attention is called to the difficulty in differentiating colonies of pneumococci from colonies of *Streptococcus viridans*. It is, therefore, Meyer says, quite likely that the variations in the percentage of pneumococcus Type IV found in normal persons may be due to difficulties of differentiation between pneumococci and green-producing streptococci.

33. The Action of Bile on the Spinal Centres.

ROSSI (*Arch. per le Sci. med.*, vol. 43, Fasc. 3-4, 1920), as the result of his experiments, found that injections of bile and bile salts into the veins and serous cavities have a depressing action on the central nervous system both of frogs and of mammals. It is only when it is injected into the carotid in large doses, or when it is brought into direct contact with the nerve centres, that bile can give rise to symptoms of motor excitement, represented by tetanic spasms, convulsive attacks, nystagmus, disorderly movements, etc. In this connexion it may be noted that states of excitement have been observed clinically in jaundice, and, experimentally, after ligation of the common bile duct in animals. In such cases, however, the phenomena of excitement may be due to special products of altered hepatic metabolism rather than to bile.

34. Congenital Paroxysmal Cyanosis.

PEHU and LANGERON (*Lyon Méd.*, November 5th, 1920) record the findings made at autopsy in a child which since birth had suffered from paroxysmal attacks (of which one proved fatal) of cyanosis, associated with intense dyspnoea, lasting as long as forty-five minutes. Physical examination during life had shown only an inconstant systolic murmur, unrelated to the incidence of the attacks. The right ventricle was found to be hypertrophied and the aorta to be dilated; the pulmonary artery was atrophic. The ductus arteriosus was obliterated, but the interventricular septum was imperfect.

35. The Properties of Histidin.

HANKE and KOESSLER (*Journ. of Biochemical Chemistry*, Baltimore, September, 1920) describe the preparation of histidin from blood corpuscle paste, and give an account of a calorimetric method by which quantities as small as 0.1 mg. can be estimated in either the presence or absence of protein. Casein, which contains a depressor substance pharmacologically similar to histidin, could not by this method be shown to contain this substance. The cerebral hypophysis of the ox, if perfectly fresh, did not contain histidin. Typical peptone shock could be obtained by injection of a peptone that was free from histidin.

36. A Microchemical Test for Ammonia.

ACCORDING to DENIGÈS (*Pharmaceutical Journ.*, October 2nd, 1920), if a very small drop of 10 per cent. aqueous solution of iodic acid is exposed for a few seconds on the tip of a glass rod to the vapour of ammonia, minute characteristic cubical crystals are formed. In very small quantities of ammoniacal salts and solution the ammonia can be detected in the following way: Take a short glass tube about 3 to 4 cm. long and 15 to 16 mm. wide, with the edge bent outwards so that it can be supported by the rim in a small flask. The solution to be tested is evaporated to about 1 c.cm., placed in the tube, and 0.5 gram of calcined magnesia added. A microscope slide on which has been spread out a drop of 10 per cent. iodic acid is allowed to stand, inverted, above the tube. If the solution contains 1 mg. of an ammonium salt, the crystals will appear in a few minutes; with 0.1 mg. in about an hour.

In Winter

'BYNOL'

For those who feel the cold.
A most palatable form in
which to take a daily ration
of active metabolised fat.

"Bynol" is a combination of Cod-Liver Oil and Malt Extract, having exceptional nutritive power. The Oil used in its manufacture is a pure product, in the preparation of which Messrs. Allen & Hanburys have been directly engaged for over half a century at Lofoten and Söndmör, Norway. Medical reports show that it is one of the best agents for arresting loss of weight and increasing capacity for assimilation.

CONTAINS 30% PURE COD-LIVER OIL
YET TASTES LIKE A SWEETMEAT.

Allen & Hanburys Limited,
37, LOMBARD STREET, E.C. 3.

Open Letters from a Layman

NUMBER THREE — THE DOCTOR and the STATE

IT is impossible to walk through the streets of our towns and villages, or even of our city slums, without being struck by the change of habit brought about by the persistent and magnificent campaign of the medical profession on behalf of the Open Window. The effect of this propaganda has been very great and entirely salutary; but of course every doctor will agree that this particular reform is but the merest beginning of that long series of personal reforms which make up the code of hygienic self-help.

Whilst appreciating to the full the great services as teachers of health which many doctors have already rendered us, we appeal to them to play in the future a very much larger and more general part in this propaganda. Probably most doctors will agree that an enormous proportion of all illness is avoidable. Even at the present stage of medical and hygienic knowledge, the sickness rates of civilized man could probably be at least halved were that knowledge embodied in the environment and habits of the people.

Now there is one man to whom, in this matter of health, all will listen. That is the doctor. We are well aware how hard worked and fully occupied with more or less routine work most doctors are. But one word from a doctor is, in its influence on public opinion, and on both public and private action, worth a column from almost any layman. In his growing zeal to become an expert craftsman, it is hoped that the physician will not forget or lose his priestly function. It is from his work as teacher that the doctor derives his name; and it is as a teacher that he can perform for his country perhaps the greatest service open to any man, or to any profession or trade. The people sicken and die largely from

lack of knowledge; and, what is even more startling, from lack of knowledge of that which is already known.

The work to be done calls for three separate forms of activity. The individual doctor must realise the importance of the part which he is privileged to play in the great work of national regeneration. Those public bodies which are concerned with hygienic administration must co-operate by organizing in every town and village in the country machinery which will simplify, economise and render most effective the doctor's efforts. And, lastly, the medical schools and the great corporations which are responsible for the training of the rising generation of doctors must see that an essential part of the education of every student of medicine shall consist not only in dealing with existing disease, but in thoroughly mastering those laws and principles of healthy living, healthy housing, healthy conditions of work and such like factors, the observance of which would prevent such illness from ever arising at all.

One word in conclusion. It is of little use to possess knowledge of social needs if this knowledge is unaccompanied by ability to impart the knowledge to others, and to bring persuasive pressure to bear on public administrators and others who peculiarly determine so many of our environmental conditions. The organised medical profession collectively resolved to make of England, so far as present knowledge and economic possibility permit, a country of healthy men and women, living in really healthy homes, leading daily lives in accordance with the necessities of real health, could achieve a revolution, by the side of which any mere economic reform would, so far as human happiness and well being are concerned, be as nothing.

J. C. ENO, Ltd., Blackfriars House, New Bridge St., London, E.C. 4.

Eno's Fruit Salt is a pleasant, effervescent, saline laxative, which bases its claim on its uniform standard of purity, on its agreeableness, and on its long record of popularity, due entirely to the experience of those who have taken it. Among those who have found it a helpful factor in maintaining a healthy activity of the digestive and metabolic functions are many doctors, both at home and abroad. Eno makes no claim to cure disease, but rather to assist in correcting some of the inevitable consequences of a civilised and artificial life to which man's physical structure has not yet become biologically adapted.

Eno's Fruit Salt is sold by chemists and stores throughout the world. A sample bottle will be sent free of charge to any medical man on application to J. C. Eno, Ltd., Blackfriars House, New Bridge Street, E.C. 4. Only by trial and experiment, can a just opinion of its quality be formed.

A British Medical Association Lecture ON THE LINES OF ADVANCE IN THE SURGERY OF BREAST CANCER.

DELIVERED BEFORE THE SHEFFIELD BRANCH ON
OCTOBER 29TH, 1920,

BY

W. SAMPSON HANDLEY, M.S., F.R.C.S.,

SCURGEON TO THE MIDDLESEX HOSPITAL AND ITS CANCER CHARITY;
HUNTERIAN PROFESSOR, ROYAL COLLEGE OF SURGEONS
OF ENGLAND.

For many years after the operation for breast cancer had passed from the primitive stage of "cutting out the lump," its development proceeded by a method of "trial and error." A surgeon by clinical observations of his failures extended the scope of his operation in this or that direction. He then devoted himself to the collection of statistics showing the result of his particular method of operation. It was hoped by a statistical comparison of the results of different operations to arrive at the "best" operation.

There can be no doubt that very considerable advances were in this way realized by American surgeons, culminating in the Halstead operation, which for some years represented the best means for the surgical eradication of breast cancer.

It will be seen that this method largely eliminates the pathologist from the scheme of things. The surgeon "guesses" his method, aided only by clinical observation, and tries it out in comparison with the guesses of other surgeons. In the comparison, statistics necessarily play a dominant part. Now the essential vice of statistics, from which even Professor Karl Pearson has been unable to redeem them, is that they assume the homogeneity of a collection of unlike things. Even granting, however, that statistics will give an accurate idea of the value of a certain operation, it has to be remembered that the possible variations of operative method are infinite in number. They can never all be tried out. Cumbersome and slow in operation, the statistical method leads firmly to an inconclusive result. As Claude Bernard long ago pointed out, statistics are not a weapon of primary importance in the search for truth, though they may supply useful secondary or confirmatory evidence.

Let me illustrate my meaning by a comparison. There are an infinity of possible routes from London to Leicester. To ascertain the best line for a railway between these two places one would not proceed by a comparison of the routes advised by different travellers with statistics of their relative times. The construction of the railway would be preceded and determined by a systematic survey of the country. It may be fairly claimed that in the application of an analogous scientific procedure to the operative treatment of breast cancer this country has led the way. The special need was detailed knowledge of the mode of spread of the disease, only to be obtained by the microscope.

Sir Harold Stiles, the pioneer who first addressed himself to this task, detected cancerous lymphatics widely diffused throughout the breast, which, moreover, he showed to be a much more extensive organ than it had been generally considered. He drew special attention to the necessity of wide removal of the pectoral fascia, while deprecating the removal of an unnecessary amount of skin. In these respects the operation suggested by him and practised by Watson Cheyne from 1892 onwards was much superior to that of Halstead. Subsequent work has required only minor modifications in it.

Stiles was prevented from reaching a general conception of the mode of spread of cancer by the defects of his material, which consisted only of excised breasts. Working on *post-mortem* subjects at the Middlesex Hospital for several years from 1903 onwards I demonstrated the centrifugal spread of breast cancer in the fascial lymphatic plexus, and detected its microscopic growing edge in this plexus at points far removed from the breast—for example, in the deltoid region, or the upper abdominal wall. The only framework which fits the observed facts is the now generally accepted permeation theory, which has replaced the embolic theory of dissemination.

A criterion is thus provided for judging any suggested operation for breast cancer, and the surgery of the disease is placed upon a completely rational basis. Technical variations in the operation, of which many are possible, must conform to the following conditions:

1. The primary growth, from which centrifugal spread begins, must always be the centre of the operation area. Thus an operation for a growth of the inner edge of the breast is not the same as an operation for a growth of the outer edge.
2. A circular area of skin 4 or 5 in. in diameter and centred upon the primary growth requires removal.

Here I may digress a moment to explain that the opinion long held, that cancer spreads along the skin, is shown by pathology to be erroneous. The apparent spread of cancer along the skin is really a punctate spread to the skin at various isolated points from the infected subjacent fascial lymphatic plexus. Since this process is secondary to and later than the spread of permeation in the fascial plexus, it follows that the area of skin infected is small compared with the area of permeation in the deep fascia. The ablation of a very large area of skin is thus shown to be unnecessary, the removal of a large area of fascia essential. I submit, with all respect to Professor Halstead, for whose work and character I have a great admiration, that in these two respects the Halstead operation erred by excess and by defect. For while he removed a large area of skin, Professor Halstead did not fashion skin flaps by undermining so as to ablate a larger area of deep fascia.

3. A circular area of deep fascia 10 or 12 inches in diameter and centred upon the primary growth must be ablated. It is first exposed by raising thin flaps of skin and subcutaneous fat, then surrounded by a ring incision, then elevated all round its edge from the deep parts until the line is reached where muscle also must be removed. The removal of a maximal area of deep fascia is demanded by the presence in this layer of the growing edge of the disease.

4. The removal of deep fascia is often too limited in the epigastric region. I have shown that this region is specially dangerous because here only a layer of fibrous tissue separates the fascial plexus from the subperitoneal fat. It is here that by direct infiltration growth often reaches the peritoneal cavity. In all cases, except perhaps with a growth of the upper edge of the breast, an area of the anterior layer of the sheath of the rectus abdominis requires removal.

Recently I was asked to see a middle-aged lady who, four months after a blow on the breast, was operated on for cancer of the breast. Thirteen months later some small nodules were detected at the lower end of the operation scar. They were excised and x-ray treatment was begun. Fourteen months after the second operation she began to suffer from dyspepsia, with pain in the left epigastric region, culminating a fortnight later in vomiting like a bilious attack. These, I may remark, are the symptoms which characterize some of the cases of invasion of the abdomen at the epigastric angle. On examination I found a recurrent nodule, near the scar of the secondary operation in the epigastric region. The left lobe of the liver was palpable and irregularly indurated. It had become infected by contact with the cancerous epigastric peritoneum. There was no other definite evidence of secondary deposits. I believe, therefore, that, had the anterior layer of the rectus sheath in the epigastric region been more widely removed, this lady might still be free of her disease.

Recurrence in the Subclavian Glands.

These glands, I may remind you, more correctly named than the subclavian artery with which they have no relation, lie at the apex of the axilla, below the clavicle, between the subclavius muscle and the upper edge of the pectoralis minor. In front they touch the costocoracoid membrane which separates them from the great pectoral muscle. On their outer side lies the axillary vein. They may be found infected in breast cancer when the lower axillary glands are still free from disease. This is due to the occasional existence of a lymphatic trunk which passes from the mammary region directly to them through the substance of the great pectoral muscle.

Recurrence in the subclavian glands presents itself in the form of a deep lump situated below the middle of the clavicle, and sometimes apparently adherent to this bone. This form of recurrence is frequent in the practice of surgeons who have not seen the necessity of clearing the axilla up to its extreme apex. In one week recently

I met with two cases of the kind. It is a form of recurrence which can be prevented with almost absolute certainty by careful axillary dissection, and the surgeon who slurs over this part of the operation incurs a heavy responsibility.

Obviously Inadequate Operations.

It is still not uncommon to see cases in which only a portion of the breast has been removed for cancer or in which the axillary dissection has been omitted. Rarely a week passes without a case of this kind coming under observation at my cancer out-patient clinic at the Middlesex Hospital. In some of these cases the lump has been considered innocent and the operator has failed to have it examined. The routine pathological examination of every supposed innocent tumour removed from the breast should never be omitted. Other cases have been in the hands of inept or occasional surgeons, who do not realize that the removal of a breast cancer is much more difficult than an appendectomy or the radical cure of a hernia. I venture to suggest that the operation for breast cancer should be left entirely in the hands of hospital surgeons, and that every surgeon who undertakes it should previously study the mode of spread of the disease.

OPERATION RESULTS.

Believing as I do that operation in breast cancer is worth doing to avert the distresses of external ulceration, even though the disease subsequently returns in the internal organs, and believing also that the interests of the individual case in this matter should outweigh the desire of the surgeon for a favourable statistical record, I have not refused operation in any case where I thought I could prolong the patient's life or make her end more comfortable.

Consequently I have no startlingly favourable results to record. Forty-eight per cent. of my cases which could be traced have remained free from recurrence for three years, as compared with 44 per cent. of Judd's and 47 per cent. of Halstead's cases. I may remark that in America cases come to operation earlier than in this country, as shown by the comparatively large percentage of cases without axillary gland enlargement in Halstead's statistics. I estimate that 90 per cent. of the cases of carcinoma which I see already have enlarged axillary glands.

It is when we come to consider the sites of the recurrence that the results become really interesting. A new type of recurrence, to which I have given the name intercostal recurrence, becomes a principal feature of the picture. Associated with this or separate from it, and even more frequently, recurrence in the supraclavicular glands is seen.

The local recurrences in and about the scar, usually multiple, which used to be found in 35 to 50 per cent. of cases of recurrence, have become rare. I confidently appeal for confirmation of this statement to any surgeon present who operates on the lines laid down by the present theory of dissemination. Cutaneous recurrences have been reduced to a very low percentage. In half the cases where they have been seen the usual prophylactic course of x rays, which I always advise, has for one reason or another been neglected. I have not seen any case of isolated axillary recurrence, nor of recurrence in the situation of the subclavian glands, and only one of recurrence in the remaining clavicular portion of the pectoral muscle. In some cases intrathoracic recurrence or return of the disease in the liver has taken place. In one case the first sign of return was in the femur on the side of the growth.

In a group of 26 cases of recurrence taken from my private notebooks, and including cases of palliative operation, the disease reappeared in the following situations:

Locally (two of these cases had escaped a proper x-ray course)	4
Supraclavicular	9
Intercostal	5
Peripheral fascial recurrence	2
Cerebral	1
Thoracic	4
Abdominal	1

Thus the majority of recurrences belong to what may be called (a) the supraclavicular, (b) the intercostal types. No case of diffuse flap recurrence—the type formerly so common—is noted.

Intercostal Recurrence.

The second common variety of recurrence—intercostal recurrence—is frequent in my experience. I am not acquainted with any precise description of this mode of return.

The first sign of it is the appearance at the inner ends of one or more of the first, second, or third intercostal spaces of small nodules, adherent to the intercostal muscles but not adherent at first to the skin. These nodules are probably an index of retrosternal deposits originating in the anterior mediastinal glands. Later on other similar nodules, also adherent to the intercostal muscles or to the ribs, appear along the first, second, third, fourth, and fifth intercostal spaces as far back as the mid-axillary line. The nodules, as they increase in size, become adherent to the skin and may ulcerate. They are distinguished from cutaneous recurrences by the fact that in their early stages the skin glides freely over them. It is obvious that they indicate lymphatic infection of the intercostal spaces, or of the anterior mediastinal glands, already present at the time of the original operation.

The interpretation of these results seems to be clear enough. The infrequency of local recurrence justifies the pathological principles of the operation. The recurrences take place beyond the range of the operation either in the anterior mediastinal or in the supraclavicular glands, less often in the viscera. It seems reasonable to infer that at the time of the original operation microscopic advance parties of carcinoma cells had already reached these glands.

We must therefore get our cases earlier, and we must devise some means of dealing with supraclavicular and intercostal recurrences either by way of prophylaxis at the time of the first operation, or by way of cure when these concealed dépôts first manifest themselves clinically.

I do not propose to deal to-night with the important matter of the education of the public in the recognition of the early signs of cancer. It would be easy to do too much in this direction and to disturb that sense of practical immortality which is one of the blessings of health in most normal individuals. We do not want to produce an epidemic of cancerphobia. What the public should know might be summed up in a few brief sentences:

After the age of 40 every individual is increasingly liable to cancer. Cancer is insidious in its onset and painless in its early stages. If taken in time, cancer may be cured by operation. If you are over 40, always get a doctor to examine you if you notice a lump or any departure from your normal state of health.

One of the principal obstacles to progress is the belief of the public that cancer cannot exist without pain. Medical men should miss no opportunity of correcting this mistake.

POSSIBLE EXTENSIONS OF THE PRIMARY OPERATION.

It would be quite possible to extend the scope of the original operation so as to include the routine exploration of the anterior mediastinum, and I have done this in six cases, all of which recovered. In only two of these did I find infected glands. In one of these two cases the growth, apparently an early one, was situated near the sternal margin of the breast. Widespread internal recurrence in the thorax took place within six months. In the other case, operated upon more than a year ago and at present free from recurrence, the glands showed irritative hyperplasia and contained a few small groups of epithelial cells.

It would thus appear that anterior mediastinal infection is present at the time of operation only in one case in three. When it is present, operative removal of the glands may fail to anticipate dissemination. For these reasons and because it increases the length and severity of the operation, I have abandoned exploration of the anterior mediastinum. Similar arguments lead me to reject the idea of routine removal of the supraclavicular glands.

Supraclavicular Recurrence.

Recurrence in the posterior triangle first manifests itself in the glands lying immediately above the clavicle and below the posterior belly of the omohyoid muscle. In examining the triangle special attention must be given to the angle between the clavicle and the posterior edge of the sterno-mastoid. Here on deep pressure an enlarged gland is often found lying in close contact with the subclavian artery. Infection of the supraclavicular glands takes place along the efferent lymphatics from the glands at the apex of the axilla, from the subclavian glands, and

sometimes from the anterior mediastinal glands. The subclavian group of glands might with advantage be renamed the infraclavicular glands. They lie, of course, behind the costo coracoid membrane. When the supraclavicular glands are once infected, extension by permeation may take place along any of the trunks—afferent or efferent—connected with them.

According to Poirier and Chaupy their lymph vascular connexions may thus be classified

Afferent Vessels.—(1) From the posterior part of the scalp and the skin and muscles of the nuchal region; (2) from the skin of the pectoral region, or even from the mammae integument; (3) lymphatics accompanying the cephalic vein which skip over the infraclavicular glands in which they should normally terminate; (4) from the axillary glands especially from the lateral chain; (5) from the cervical portions of the larynx, trachea and oesophagus; (6) from the pretracheal glands of the neck; (7) aberrant vessels of the internal mammary chain which normally discharge into the great veins; (8) occasionally from the chain of glands lying along the external jugular vein; (9) from the small glands lying in the thorax which accompany the recurrent laryngeal nerves.

Efferent Vessels.—These unite with the efferents of the sterno mastoid glands to form a common trunk, the jugular trunk which joins the confluence of the internal jugular and subclavian veins.

It will be seen from the foregoing account that cancer cells which have reached the supraclavicular glands have attained a favourable strategic position for the extension of their attack on the body in various directions. They frequently penetrate to the external jugular and the occipital glands, and the union of the efferent trunks from the supraclavicular and the sterno mastoid glands affords opportunities for the invasion of the latter set of glands which lie along and external to the internal jugular vein. Supraclavicular infection thus is the precursor of wide infection of the neck, and even of the cranial cavity.

In regard to the thorax the position is less unfavourable. It seems doubtful whether any direct vascular connexion exists between the pretracheal glands of the thorax and the supraclavicular glands. In many cases the pretracheal efferent trunks discharge directly into the great veins, and the avenue of permeation into the lymph is thus cut off. It would seem that the only constant lymph vascular connexion of the supraclavicular glands with the thorax is by way of the efferents of the small recurrent laryngeal chain of glands. This conclusion is an important one, for it justifies the hope that, as experience has now shown, a vigorous attack on enlarged supraclavicular glands may anticipate and prevent invasion of the thorax. If, however, periglandular infiltration with fixation of the enlarged glands has taken place, it is likely that infiltration of the dome of the closely adjacent pleura has occurred, and in such cases operation is useless.

The definite break in the continuity of the permeation channels imposed by the separate termination in the great veins of the lymphatics of the neck and of the thorax respectively is, as we have seen, a great encouragement to the surgeon who contemplates an attack upon supraclavicular glands. The complexity and extent of their lymph vascular connexions in the neck is a factor which at first sight seems very unfavourable to operation. But all the glands in the posterior triangle are within operative reach, and so, too, are the deep or internal jugular glands. Acting on the advice of the late Sir Henry Butlin, I have for some years made it a rule in cases of infected supraclavicular glands to perform a complete lymphatic dissection of the posterior triangle, including also the internal jugular glands. The glands are removed in one piece still embedded in the connective tissue, and therefore with all their lymph vascular connexions intact.

Treatment of Supraclavicular Recurrence.

There can be no doubt that the right treatment of supraclavicular recurrence in its earlier stages is operative. The operation must however, be a very thorough and systematic one. On the other hand, it is futile to attempt the operative treatment of late cases of supraclavicular recurrence, where the growth has infiltrated the gland capsule and has passed into the surrounding tissues.

Broadly speaking if the glands are mobile they should be operated upon, if they are fixed they should be left alone. But if the only fixed gland is situated at the lower and inner angle of the posterior triangle it is sometimes worth while attempting to enucleate it and if the attempt is successful and a tube of radium is introduced into the

bed from which it came, a long period of freedom from recurrence may be secured, provided at the same time all the glands in the posterior triangle are removed.

The use of radium in the operation wound should never be omitted in any operation for supraclavicular glands. It minimizes the great risk of these operations, namely, that of general implantation of carcinoma cells on the raw surface and the subsequent development of a general boardlike carcinomatous infiltration of the field of operation—an unfortunate result which may follow operation in too late a stage.

The boundary line between the operable and inoperable cases, though broadly fixed by the mobility or fixity of the glands, has been pushed forward definitely by the use of radium tubes in the operation wound. In doubtful cases the decision should now be for operation, instead of, as formerly, against it.

It must be borne in mind that subsequent recurrence, say, in the thorax, does not necessarily imply the failure of the operation. Besides its main object, the eradication of the disease, it has an important secondary object—namely, to avert the agonizing brachial neuralgia which is so often seen in the later stages of supraclavicular recurrence. If this object is attained the operation has justified itself, even if the patient dies of some other manifestation of cancer.

The question arises, therefore, whether operation on enlarged supraclavicular glands should be undertaken even in cases where other secondary deposits are known to exist. As a rule this question must be answered in the negative, for in such cases the period of survival is likely to be a short one, and death may occur before pressure on the brachial plexus has had time to develop. It seems better in such cases merely to attempt to delay the development of the supraclavicular deposits by the use of buried radium.

Radiation in the Treatment of Breast Cancer.

In a disease which has such wide spreading microscopic manifestations as breast cancer, surgical extirpation, though it remains our best resource, is evidently a clumsy weapon. It has for some years been supplemented by post operative radiation by x rays. For the past fifteen years I have uniformly advised post operative radiation, and my experience shows that cutaneous and subcutaneous recurrence is more likely to occur in cases which have escaped, for one reason or other, this prophylactic course. My practice has been to advise only a short course followed after an interval by a second course.

It is now known with certainty that by an adequate dose of radiation a mass of cancer cells can be killed, and the idea which has hitherto for the most part governed the use of radiation is the destruction of any groups of cancer cells remaining after the operation.

It would of course be preferable, instead of destroying the seed so to alter the soil as to make its growth impossible—in other words, to immunize the patient against his own cancer. For a long time I was sceptical as to this possibility, for whereas in the older parts of a breast cancer degenerate malignant cells enveloped by round cells or by fibrous tissue are normally found in large numbers, at the actual growing edge of the disease there is no round celled infiltration. Here the healthy active cancer cells have excited no visible reaction and they appear to be accepted as normal denizens of the body. I inferred a close family likeness between the cancer cell and the normal epithelial cell which rendered unlikely the success of attempts to produce immunity against the cancer cell.

It remains a fact that no marked success has attended attempts to induce immunity in an animal against its own spontaneously occurring growth. Nevertheless, the aspect of the problem has lately become more hopeful, largely owing to the work of Professor Russ and his fellow-workers in the Middlesex Hospital Cancer Research Laboratories. Starting with the idea that the tumour substance itself removed, suitably irradiated, and then inoculated might prove to be an immunizing agent, Russ inoculated the irradiated tumour substance. Subsequently in a large percentage of cases the animal is found to be immune to a further inoculation of the active virulent tumour substance, which in a control animal would give rise to a large tumour. These results apply to mouse carcinoma and rat sarcoma.

irradiation, and even before she left London—that is three weeks after the application—the supraclavicular lump had shrunk to half its original size, the ulcerated patch had improved considerably, and the sternal thickening could not be felt. A skiagram taken in Bath in 1918 showed suspicious thickening of the root of the left lung, and I was not at all sanguine as to the future. In August, 1919, a small nodule appeared below the right clavicle. In October, 1919, the patient was sleeping wonderfully well, but after a severe cold Dr. Stalker detected some dullness at the left base.

On November 1st, 1919, I saw this patient at her home in Scotland. About three weeks previously she had had a bronchitic attack, with pain at the base of the left pleura, and here a little fluid was present. Her general condition previous to this attack had been so good that she was driving out daily, sometimes in an open vehicle. She was sleeping well and was free from pain. On the left side of the chest—that originally affected—no overt sign of malignant disease remained. In the left supraclavicular triangle and the left axilla no glands could be felt, though above the clavicle large glands had been present prior to the radium treatment. The ulcer, with surrounding nodular deposits, though still open, had partly healed, and was quite flat and innocent as to its base and surroundings. No trace of the original large sternal swelling remained. On the right side, however, though the intercostal deposits in the second and third spaces had disappeared, the disease had made progress under the right breast. Here a large mass was present, with a smaller one in the upper and outer quadrant. The large fixed gland in the lower and inner angle of the posterior triangle—treated six months previously—had disappeared. Over the middle of the right clavicle one small nodule had appeared. The whole right breast was heavy from lymphatic oedema and the nipple swollen. There was some fullness over the lower part of the sternum never noticed before. Radium, 1 mm. screen, for twenty hours was introduced—100, 50, 20, and 10 mg. in various situations beneath the right breast, 10 and 10 mg. at the right edge of the sternum, 10 mg. in the nodule beneath the clavicle.

Though the dullness at the left base was very suspicious, the general condition was excellent, the patient cheerful, and her colour good. The lymphatic oedema of the breast rapidly subsided. In January, 1920, the patient was sufficiently well to travel to Bath and to come down regularly to the family dinner. While at Bath sternal swelling recurred and the right breast became oedematous. A further dose of radium repressed these external manifestations, but signs of rapid pulmonary involvement, with dyspnoea and increasing dullness at the left base, showed that the end was approaching. In April, 1920, she returned to Scotland. Temporary improvement followed, but she died early in May, 1920.

She certainly owes to radium more than two additional years of comfortable and even enjoyable existence, though the treatment was begun when she had been given only a few months to live. A ray and open air treatment were used throughout as adjuncts.

CASE III.—*Recurrence after Operation for Carcinoma Mammæ: Radium, X Ray, and Operative Treatment: Three Years Later no Sign of Active Disease.*

In September, 1916, I operated on Mrs. D., aged 60, for a rather advanced carcinoma of the upper and outer quadrant of the right breast. A section confirmed the diagnosis. She subsequently had x ray treatment by Dr. Prowse of Brighton. In March, 1917, she developed a thickening, soon becoming definitely nodular, over the sixth right costal cartilage. Another nodule appeared higher up at the edge of the sternum. The nodules disappeared completely after the insertion in June, 1917, at the site of each for twelve hours of a 50 mg. tube of radium with a 1 mm. platinum screen. In September, 1917, there was some general swelling of the arm, but not to a serious extent. In October, 1917, Mr. I. detected a lump at the outer edge of the th. A x rays failed to reduce this nodule, and I excised it. A section showed degenerate but still living carcinoma cells. All this time the patient's general health was good and she had very little pain. In July, 1918, a lump appeared in the right supraclavicular region, and this was successfully treated by burying a tube of radium. In December, 1918, a skiagram of the chest by Dr. Prowse showed no sign of secondary deposit. Her husband wrote that she "seems wonderfully well and certainly looks it." The slight swelling of the arm continued much as it was, with variations from time to time. Up to November, 1920, this lady had developed no fresh signs or symptoms. Thus three and a half years after the first recurrence the disease remains in abeyance, and meantime the patient has lived a comfortable and almost normal life.

CASE IV.—*Supraclavicular Recurrence Successfully Treated by Operation and Radium: Death from Thoracic Deposits.*

Mrs. H., aged 59, was sent to me by Dr. Simpson, of Grosvenor Street, in January, 1914. In the previous year another surgeon had removed a carcinoma from the left breast. She now had enlarged glands in the left posterior triangle, which upon removal on January 4th, 1914, were found to be carcinomatous. In April, 1914, her general condition was satisfactory and she was free from pain, but two or three small nodular recurrences were present in the posterior inferior angle of the posterior triangle. They were treated by burying a tube of radium. Radium treatment was repeated in 1914, and in November, 1914, the nodules had disappeared. About this time she had developed

bronchial symptoms, and she shortly afterwards died with thoracic recurrence. In this case radium combined with operation probably averted pressure upon the brachial plexus and thus made the patient's end a comparatively easy one.

CASE V.—*Recurrence in the Left Supraclavicular Glands: Excision and Radium Treatment. Rapid Recurrence at the Base of the Left Pleura.*

Mrs. H., aged about 45, was sent to me in 1916 by Dr. Hobart of Cork. The left breast had been removed for carcinoma in 1914. The left supraclavicular glands were hard and enlarged. There was no other sign of recurrence. I excised the glands, leaving a tube of radium in the wound for twenty-four hours. Three months later there was evidence of pleural growth at the base of the left lung, and the patient did not long survive. There is, however, reason to think that the operation saved her from nerve pressure upon the brachial plexus. This case illustrates the disappointments that may be met with in the treatment of recurrence, and shows that an x ray examination of the chest should always precede operation in such cases.

CASE VI.—*Intercostal and Supraclavicular Recurrences Suppressed by Radium. Later Signs of Thoracic Metastases.*

A. B., aged 55, was operated upon by me for cancer of the left breast in August, 1915. In December, 1917, a lump appeared in the second left intercostal space, but she ignored it until March, 1919. In April, 1919, two 50 mg. tubes of radium were introduced into the first and second space, and by June 16th the lump had disappeared. In October, 1919, there was no return, but slight prominence and tenderness had appeared over the right half of the first piece of the sternum and radium tubes were introduced here. In November, 1919, the patient came up stating that she had never been so well before, but on examination two hard glands were felt in the left supraclavicular triangle. On January 1st, 1920, four tubes of radium, 200 mg. in all, were introduced into the left supraclavicular triangle, the left axilla, and the right sternal region. On March 3rd, 1920, no glands whatever could be felt, but there was shortness of breath and some dullness at the left base; probably there is infection of the lungs and pleural cavity and the patient's days are numbered. But radium has kept her comfortable almost to the end and has given her an extra year of enjoyable life.

CASE VII.—*Intercostal Recurrence: Improvement under Radium Treatment.*

C. A., aged 68, was operated upon for carcinoma of the right breast at St. George's Hospital in 1917. In March, 1919, she attended the Middlesex Hospital for a recurrent fluctuating mass with reddened skin at the inner end of the fourth right intercostal space. It was incised, but no pus escaped, and was evidently a mass of degenerate growth. She was admitted for radium treatment, and in June, 1919, only a thick scar remained at the site of the lump. In October, 1919, the lump was again increasing, and there was vague induration of the left breast and enlargement of a left axillary gland.

CASE VIII.—*Intercostal Recurrence: Radium Treatment. Relapse after Great Initial Improvement.*

Kate G., aged 59, was operated upon in January, 1913, for carcinoma of the left breast. In March, 1914, a swelling was noticed over the manubrium. In June, 1914, two 50 mg. radium tubes with 2 mm. screens were inserted for twenty-four hours. A second application was given in November, 1914. In December, 1914, the lump over the sternum had disappeared except for one slight local thickening. In February, 1915, there was no sign of growth, but in May, 1915, there was some thickening at the left margin of the sternum. The patient shortly afterwards ceased to attend.

CASE IX.—*Late Intercostal Recurrence: Successful Treatment by Radium: Patient Well Two Years Later.*

A. L., aged 58, was operated upon in 1926 by Sir A. Pearce Gould for carcinoma of the left breast. She remained well until September, 1918, when a lump appeared at the inner end of the second left intercostal space. It was a fixed induration adherent to the bones. On November 23rd, 1918, a 50 mg. tube of radium with 1 mm. platinum screen was buried under the lump for twenty-four hours. On December 1st the lump was much smaller, and on April 9th, 1919, no trace of a lump could be detected. In January, 1920, there was no trace of a return of the lump, but a suspicious fullness was present over the inner end of the first space. In March, 1920, tubes of radium were buried at the inner end of the first and third spaces in order to anticipate events. Patient remains well (June, 1920).

This case goes to show that the later the time at which the recurrence first appears the more likely is it to be amenable to radiotherapy. This impression cannot yet be submitted to a statistical test.

CASE X.—*Intercostal Recurrence Seven Years after Primary Operation: Disappearance under Radium.*

A. G., aged 52, attended at the Middlesex Hospital in February, 1920, for a fixed intercostal recurrence in the second left space. The left breast had been removed for carcinoma seven years previously. After radium treatment the sternal recurrence completely disappeared, but an enlarged gland could now be felt in the lower and inner angle of the left posterior triangle.

CASE XI.—*Intercoastal Recurrence Refractory to Radium Treatment.*

Emma M. in June, 1916, was operated upon for carcinoma of the right breast. She attended the Middlesex Hospital in July, 1917, for a typical intercoastal recurrence in the first right space. Two 59 mg. tubes of radium with 3 mm. screens were introduced into the lump on November 7th. In the following January no diminution in the lump had occurred, and in February the lump involved the second space as well as the first, and recourse to sedatives was necessary.

This case suggests that results are better with a 1 mm. screen than with a thinner screen, a suggestion borne out by my experience in other cases.

CASE XII.—*Intercoastal Recurrence One Year after Operation: Treatment by Secondary X Rays: Patient still Well, Ten Years after First Operation.*

Mrs. D., aged 61, noticed in 1909 a small kernel in her right breast. She consulted me in March, 1911. A lump 1½ in. in diameter, adherent to the fascia, was present in the upper and inner quadrant of the right breast. The glands in both axillae were enlarged, especially those on the right side. The growth proved to be a cellular one of duct origin, and many of the epithelial masses showed central degeneration. Prophylactic x rays were given after the operation. In May, 1912, nodules were noticed in the second, third, and fourth right intercoastal spaces at their inner ends, and one or two nodules further out along the intercoastal spaces. Bismuth carbonate injections were made at the inner ends of the affected intercoastal spaces, and subsequently another course of x rays was given. The patient followed my advice to live an open-air life. By September, 1912, no trace of the nodules remained. One doubtful nodule was felt over the upper end of the sternum, and here and in the fifth intercoastal space, where a slight thickening remained, bismuth was again injected. The x rays were continued.

There was no doubt of the recurrence, for the nodules were definite and rounded. At the present time (January, 1920) there is no trace of them, and the patient remains well. In 1918 she had some enlargement of the left axillary and supraclavicular glands, but this has subsided under x rays. The method of secondary x rays employed in this case has been superseded by the use of radium.

CASE XIII.—*Intercoastal Recurrence Five Years after Operation for Breast Cancer: Radium Treatment; Patient Well nearly Two Years Later.*

Mrs. S., aged 28, noticed early in January, 1912, a lump in the left breast. She consulted me on January 18th, 1912. There was no skin adhesion but some fascial fixation, and very marked mastitis in the right breast. Preliminary exploration showed that the tissue looked like mastitis, but immediate examination showed it to be malignant. The great pectoral was removed except uppermost clavicular fibres, and the lesser pectoral and serratus left. The supraclavicular region was not explored. A small piece removed from the right breast was innocent chronic mastitis. Prophylactic x rays were given after the operation. In October, 1912, there was no sign of recurrence whatsoever and perfect mobility. The patient, who was a keen sportswoman, played golf during the summer, and won two medals within six or seven months of the date of operation. In 1917 there was a tiny lump at the junction of the upper border of the left second costal cartilage with the sternum, and the patient was given another course of x rays. In December, 1918, there were two small recurrences in the second and third left intercoastal spaces. The patient had been doing very hard muscular work which may have predisposed her to these. I removed the recurrence in the second space and had it microscopically examined. I put in two tubes of radium, one in each space, and a week after the nodule in the third space had disappeared.

At the present time (October, 1920) there is no recurrence, and the patient looks well.

Question of Treating Operable Breast Cancer by Radiation.

I have met with one case in which a persistent effort was made to treat a carcinoma of the breast by x rays without operation.

CASE XIV.—*Operable Cancer Unsuccessfully Treated by X Rays.*

Mrs. A. noticed a lump in the left breast in 1913. In the summer of 1916 she consulted a medical man who has had extensive experience in x rays, and who made a diagnosis of cystic disease of the breast. X rays were applied to the breast on fourteen occasions. The lump became smaller and a pucker appeared on the skin. The patient was thereupon advised to consult me. I saw her in January, 1917, and found a puckered scar over the upper and outer quadrant with slight subjacent induration. There was no adhesion to fascia, and no glands were felt. Section after operation showed a carcinoma. The epithelial cells were in small groups and many of them were degenerate. The glands were unaffected.

Apparently in this case the radiation exerted a deterring and delaying effect on the growth, and perhaps prevented its spread to the axillary glands; but there was no evidence of cure. The history of this case goes to justify the belief usually held that operable cancer should not be treated by radiation only. The exceptions to this rule

are (1) if the patient refuses operation; (2) in old and feeble subjects with atrophic cancers; (3) grave constitutional disease—for example, cardiac or renal disease or diabetes.

Treatment of Inoperable Primary Growths by Radium.

In cases where operation is excluded by the advanced stage of the growth, age, or constitutional disease, much benefit may be derived from the use of buried radium. The primary growth may even completely disappear, or short of this ulceration may be averted, a very great gain to the patient's mental and bodily comfort. So far, however, there is no proof that by the imperfect methods at present in use the spread of the disease is arrested.

The following cases illustrate the treatment of inoperable growths by radium:

CASE XV.—*Advanced Primary Growth of Breast: Great Local Improvement after Radium.*

A. H., aged 37, attended the Middlesex Hospital in December, 1914. The whole of the right breast was infiltrated by carcinoma and firmly adherent to the chest wall. There were very numerous nodules around the breast, and especially on the outer side. A mass of enlarged glands was present in the axilla and just above the clavicle. On December 9th, 1914, four tubes of radium, 187 mg. in all, were inserted into the right breast for twenty-four hours. On January 26th, 1915, the infiltration of the breast had almost disappeared and the organ had become freely movable; the nodules also were shrunken. Two slight areas of radium dermatitis were present over the sites of the insertion of the tubes. The patient ceased to attend.

CASE XVI.—*Inoperable Cancer of the Breast Treated by Radium: Marked Local Improvement, but Continued Centrifugal Spread.*

M. A. S., aged 49, attended the Middlesex Hospital in November, 1916, with an ulcerated mass in the lower part of the right breast and universal induration of the breast. There were hard glands in the axilla. In December, 1916, radium was inserted into the axilla and breast. The glands disappeared within a month, and the upper part of the breast was soft and slack. Growth reappeared in the supraclavicular region, and in January, 1917, extensive nodular skin deposits were present around the breast. Further treatment was deemed useless.

This case well illustrates the usual history of carcinoma of the breast treated by radium alone. There is marked local improvement, but the centrifugal spread of the disease continues unaffected. Such cases appear to show that, if possible, treatment by radium should be applied first to the peripheral growing edge, and later in a centripetal manner to the primary growth. But the practical difficulties involved are great.

CASE XVII.—*Inoperable Carcinoma of the Left Breast: Radium Treatment: Disappearance of the Primary Growth, but Extension of Growth in the Glands of the Axilla and Neck in spite of X Rays.*

A. A., aged 61, attended the Middlesex Hospital in July, 1915, for a lump in the axillary margin of the left breast. The skin was adherent and the supraclavicular glands on the left side were much enlarged. Treatment by buried radium. In October, 1915, the supraclavicular glands were palpable and hard, but not enlarged, the primary tumour had disappeared, leaving only a vague induration. In December, 1915, no lump whatever could be felt in the breast. In April, 1917, the primary growth had not recurred, and there was merely an adherent scar, but there were large masses of nodular glands in the axilla and above the clavicle. X-ray treatment was being continued.

This interesting case illustrates that the complete disappearance of the primary growth does not mean the arrest of the disease. I have seen the same thing happen after radium treatment of carcinoma of the lip—complete cicatrization of the primary growth, and later the appearance of a mass of secondary glands.

CASE XVIII.—*Disappearance of Primary Growth under Radium.*

Mary W., aged 49, attended the Middlesex Hospital in February, 1916, for a cancer occupying the centre of the left breast. Radium was inserted on February 29th, and on March 29th the growth had disappeared, though glands could still be felt in the axilla and supraclavicular region, subsequently lost sight of.

CASE XIX.—*Carcinoma Treated by Radium without Operation: Growth in Check Two Years later.*

F. A., aged 60, in June, 1917, noticed a lump in the left breast. In June, 1918, when she sought advice, there was a carcinoma in the breast the size of a large orange, immovable and attached to the skin. The glands in the left axilla were enlarged. She refused operation and was admitted in August, 1918, for treatment by buried radium tubes. On September 11th the breast was much smaller, softer, and more mobile—an extraordinary improvement. In October, 1918, an induration, possibly a second primary carcinoma, appeared in the upper and outer quadrant of the opposite breast, and she was sent for x-ray treatment. In April, 1920, no further developments had occurred, and the growths appeared to be still in check.

Radiation as a Preliminary to Operation.

Dr. N. S. Finzi believes that it is advisable to give a large dose of α rays just prior to operation, and I am inclined to think that the practice is a sound one, though its value is not easily susceptible of proof. It should not be allowed to delay operation. Recent work at the Middlesex Hospital goes to prove that the resistance of the patient to carcinomatous infection may be increased by a small dose of radiation prior to operation.

There is no doubt that radiation frequently converts an apparently inoperable tumour into an apparently operable one. I have met with three such cases during the past year.

Natural Cure of Cancer in Relation to X-Ray Treatment.

It is not possible to form a correct estimate of the value of radiation in cancer without taking into account the natural tendency of the disease to undergo local repair. In a lecture on this subject I came to the conclusion that "Every aggregation of cancer cells, after increasing in size for a varying period and for a varying rate, tends spontaneously to undergo certain degenerative or regressive changes. These changes begin at the centre of the mass, spread centrifugally to its circumference, and may terminate in the replacement of the mass of cancer cells by a fibrous scar."

These changes, which are exemplified in the ulceration of a primary growth and in the umbilication of secondary deposits in the liver, appear to depend upon a breakdown of the improvised vascular commissariat of the growth and upon the harmful internal pressure produced by the active proliferation of the cancer cells. These degenerative changes can be seen beginning even when the collection of cancer cells is still of microscopic size, as is a permeated lymphatic. Their onset is invariably accompanied by the advent of collections of lymphocytes to the neighbourhood. It is thus possible that in every carcinoma we have to deal with a comparatively small number of perfectly healthy and active cancer cells and with a large mass of more or less degenerate and dying cells. The former class of cell is to be found in the permeated lymphatics of the microscopic growing edge and at the edge of microscopic nodules of growth which are still in the actively infiltrating stage. It seems likely that these two classes of cell differ widely in their reaction to radiation. It is probable that the crowds of degenerate cells which constitute the mass of a carcinoma may fall a ready prey to the reaction of radiation. Even the earliest attempts at the destruction of secondary nodules by α rays were often locally successful. The shrinkage and disappearance of local masses of cancer may possibly indicate nothing more than the acceleration and completion of this natural process of destruction.

The Prophylactic Use of Radium at the Time of Operation.

Having considered and rejected the idea of extending the scope of the primary operation to include removal of the supraclavicular and the anterior mediastinal glands, I determined at the end of 1919 to try another plan to meet the deplorable frequency of intercostal and supraclavicular recurrence.

If in a considerable proportion of cases, at the time they come to operation, microscopic colonies of carcinoma cells are present in these glands, it may be fairly hoped that vigorous irradiation applied to the glands as directly as possible may destroy these colonies. There is the further possibility that a general immunizing action may be at the same time secured.

Prior to the closure of the main operation wound, a 25 mg. tube of radium is pushed under the intercostal fascia at the inner end of the first space. A similar tube is placed in the same way at the inner end of the second space, and it might be advisable, if a third tube is available, to place it at the inner end of the third space. The threads attached to these tubes are brought out through the line of incision or through separate stab wounds, as may be convenient. A 50 mg. tube of radium is now introduced under the deep fascia in the lower and inner angle of the posterior triangle, the situation where the first evidence of supraclavicular recurrence is usually found. This tube is introduced through a small stab

wound. The radium is screened with 1 mm. of platinum; it is left in place for twenty-four hours and is withdrawn at the first dressing.

The following is the first case in which I used the method.

CASE XX.

A young lady of 32, six months pregnant and in vigorous general health, was brought to me in December, 1919, with a rapidly growing mastitic carcinoma of the upper and outer quadrant of the left breast. The axillary glands were enlarged. The growth was evidently very malignant, and the pregnancy as well as the youth and vigour of the patient made the outlook a bad one, but I urged an immediate operation, to be combined with the use of radium, and my advice was accepted. The pregnancy continued undisturbed, and resulted in a very fine healthy infant. Subsequently α rays were administered by Dr. Finzi. A section showed an exceedingly active and cellular growth with hardly any stroma. The patient was not permitted to suckle her child. At present (November, 1920), nearly a year later, she remains well.

This case was exactly of the type in which an early fulminating recurrence seemed inevitable, and its result to date is distinctly encouraging. I have since made the use of prophylactic radium a routine practice wherever possible. If the method establishes itself it will be necessary for surgeons dealing with breast cancer either to possess or to have access to the necessary amount of radium.

The use of radium in this way seems perfectly safe, if it is kept well away from the skin. The only drawback I have to report is that in several cases brachial neuralgia, lasting for several months, and accompanied in one case by a small trophic slough in the region of the elbow, has occurred. I shall therefore, in future, use a 25 mg. tube instead of 50 mg. in the supraclavicular triangle, and as a security against secondary radiation I propose to enclose it in a rubber sheath.

I await the results of this method with interest and hope, encouraged by the fact that no recurrence has yet taken place in any of the cases treated during the past year.

Open-air Treatment.

In conclusion, I should like to urge the importance of open-air treatment, both for its prophylactic value against recurrence and in the more chronic varieties of inoperable cancer. In cancer, as in tubercle, the natural defences of the body are to be partly found in the processes of inflammatory and fibrotic reaction. Clinical experience of the value of open air in tubercle shows that these processes are stimulated by fresh air.

ABSTRACT OF A LECTURE

ON

SUBACUTE BACTERIAL ENDOCARDITIS.*

BY

BASIL PARSONS-SMITH, M.D., M.R.C.P.,

PHYSICIAN TO OUT-PATIENTS, THE NATIONAL HOSPITAL FOR DISEASES OF THE HEART; HEART SPECIALIST, MINISTRY OF PENSIONS.

The subject of this lecture—subacute bacterial endocarditis—has been selected primarily because it happens to be one of those states of disease which warrants a wider recognition, and because clinical observation and experience offer abundant and ever-increasing evidence of the high rate of incidence of the condition. In spite of the mass of convincing and definite conclusions arrived at by the pioneer investigators, subacute bacterial endocarditis is a disease which is very frequently overlooked entirely. To some extent this may possibly be accounted for by the fact that the condition is one of slow and insidious onset, more often than not arising in patients already suffering from cardiac disease itself of such a nature as to explain apparently, in perfectly satisfactory fashion, any degree of cardiac failure which may be present. Valuable indications, however, later to be discussed, enable us to realize that valvular lesions, typically quiescent, may become the seat of a fresh infection which will influence profoundly the whole outlook of the patient, and materially alter the prognosis. The whole position will be simplified if we are prepared to appreciate the presence of signs of active infection in patients suffering from a hitherto quiescent lesion.

* Delivered at the National Hospital for Diseases of the Heart, November 29th, 1920.

Real and weighty difficulties do, however, exist, for it must be admitted that we are still very far from the day when exact and tangible evidence will definitely enable us to understand and appreciate the features significant of the actual onset of infective endocarditis of the subacute variety. At the moment our situation is unsatisfactory. Certainly we can diagnose the disease without difficulty in its fully developed form by signs and symptoms which are unmistakable in character, but we know full well that this stage of the malady having been reached there can only be a fatal termination.

Obviously, therefore, it is our business as clinicians to search most carefully and assiduously for early indications of the presence of the infective process, for it would seem that, unless we can perfect our knowledge from this point of view, our chance of being able to employ successful treatment is exceedingly remote.

Before describing in detail the more important features of the subacute variety of bacterial endocarditis, it will possibly be of some advantage to review for a moment our conception of the types of disease which result from endocardial infections.

It is customary to divide endocarditis into two main groups: (1) The simple or benign; (2) the ulcerative, infective, or malignant. This division is arbitrary: useful from the clinical standpoint but of little value as regards etiology, pathology, or morbid anatomy.

The underlying process is similar, but the degree of intensity varies in the two groups, and all gradations are represented. In the milder forms of the disease organisms are not found; this may reasonably be explained by the fact that endocarditis is known to run a latent course in certain cases without modifying the symptoms of the primary affections to any appreciable extent, so that the early stage is altogether missed. Here we may suppose that the endocardial damage is either the work of short-lived organisms—very possibly of low virulence—or the result of the spread of toxins in the circulation. The endocardial damage, which is so frequently associated with acute rheumatism, exemplifies this benign or simple category. Here the early infection betrays itself unmistakably: the fever, which may have subsided, develops again, the pulse becomes rapid and irregular, the apex beat is noticed to be wavy and forcible, extending well outwards to the left, the shock of the heart sounds is exaggerated, and the sounds themselves become blurred in character. These signs are indicative of the first stages of endocardial infection; the later developments vary in individual cases, giving rise to all degrees of incompetence—myocardial, valvular, etc.

With regard to the second group—the ulcerative or malignant type of endocarditis so-called, in which the heart lesion is secondary to, rather than responsible for, a systemic pyaemia or septicaemia—a brief statement will suffice to explain the sequence of events which, taken collectively, constitute this grave disease. First, it is necessary to assume some primary focus of acute infection, a generalized blood invasion therefrom, and secondary lesions, ulcerative in character, of the cardiac valves or endocardium; depending largely upon the seat of the primary focus, also upon the variety of organism concerned, we must of necessity be prepared for physical signs widely varied in type, hence the grouping, which has been adopted from the clinical standpoint, into the three types—cardiac, pyaemic, and typhoid. We need not proceed to discuss these in detail, the special features which characterize each can be appreciated without difficulty; suffice it to say that the disease, in any of its forms, progresses with extreme rapidity, the duration usually being limited to a few days or weeks.

Subacute bacterial endocarditis may be said to occupy a position midway between the simple and the fulminating types of the disease; its title is fully descriptive, and will at once suggest in some measure the clinical aspect of the condition.

During recent years this variety of endocarditis has attracted considerable attention; an increasing number of cases seem to come under observation. One should not, however, conclude, without very careful investigation, that this disease is becoming more frequent in incidence, for in dealing with this matter several factors must be faced, not the least of which is our conviction that fewer cases are overlooked nowadays than formerly. We are tending, in fact, to become more familiar with the disease, and

there is a general agreement that diagnosis need present no difficulty, so characteristic is the clinical aspect of the condition.

The onset of the disease is usually insidious, and symptoms are not necessarily pronounced. An ill-defined malaise, general debility with loss of strength and tone, erratic and fleeting pains in the joints or limbs—each of any of these may be the only indication from the patient's point of view of the earlier stages of the disease. Symptoms of cardiac failure—dyspnoea, palpitation, giddiness—may be noted, but as often as not will fail to manifest themselves until the disease has become fully developed. One realizes, therefore, that the symptoms of subacute bacterial endocarditis are far from being precise—in fact, more often than not they appear to be extremely vague. Not so the physical signs, which present an unmistakably clear clinical picture: examination of the heart shows in every instance the presence of an organic murmur at the aortic or mitral regions; apart from the murmur, the heart may show little or no evidence of functional disturbance during the course of the disease; beyond a simple tachycardia the rhythm, as a rule, remains unaffected, the myocardium retains its power, venous stasis does not develop—in fact one may follow the entire progress of the disease without noting at any time a full development of the true signs of cardiac failure. In other words, we can very reasonably conclude that the endocarditis does not represent or explain, in anything approaching adequate fashion, all the signs and symptoms which we have learnt to associate with this disease, and furthermore we can readily understand the prevailing idea of the nature of the malady—namely, that it is a general systemic disease depending upon a bacterial invasion whose seat of origin is localized at some focus of chronic or quiescent valvulitis.

Clinically, therefore, we may expect in this type of case to find a series of important signs which we are not in the habit of associating with valvular disease of the heart in its uncomplicated forms: pyrexia will be present at some period during the progress of every case; the type of curve is irregular, remissions and apyrexial intervals are frequent, rigors and sweats are common. Examination elicits numerous confirmatory phenomena; of these there are three—namely, pallor, enlargement of the spleen, and clubbing of the fingers—which, taken together, may conveniently be referred to as the diagnostic triad of the disease. The pallor suggests a profound secondary anaemia, and the dusky sallow tinge is indicative of the septicaemic state. The clubbing of the fingers and toes is insidious in onset, develops later with extreme rapidity, and, curiously enough, the patient is as often as not quite oblivious to the change which is in progress; the regularity of this sign will at all times materially assist diagnosis.

Other signs are forthcoming during the progress of the disease, and include multiple arterial embolism, renal insufficiency, haematuria, positive blood culture, sternal tenderness, loss of weight, progressively increasing anaemia, and, accompanying the secondary lesions in the final stages, varying degrees of leucocytosis.

Time does not permit an exhaustive description of the large variety of embolic phenomena which characterize this disease; objectively we recognize their presence without difficulty in the majority of instances; especially is this so with infarction of moderate sized vessels, as, for instance, those of the spleen, kidney, brain, or extremities. Other emboli, however (the smaller varieties and those microscopic in size) produce results equally significant—cutaneous petechiae, painful nodes, and discoloured patches on the terminal phalanges of the hands and feet, arthritic inflammations, embolic aneurysms, etc.

A blood culture must be attempted in every case that comes to our notice, but a negative result should not deter us from further efforts to cultivate the organism. In spite of the fact that we have as yet insufficient evidence to dogmatize, I feel that the variety of endocarditis at present being considered is not the result of any one specific organism; several types have been found, including pneumococci, gonococci, the influenza bacillus, and small streptococci. In the opinion of Libman, whose researches entitle him to speak with authority, these subacute varieties of endocarditis are due to the *Streptococcus anhaemolyticus* in about 95 per cent. of the cases. The other 5 per cent. are due mainly to the influenza bacillus; but an additional case will be due to the gonococcus or *Micrococcus flavus*.

It does happen, however, that the blood culture is persistently returned as negative in certain cases of indisputably infective endocarditis. The explanation for this is not easy; three suggestions may be made:

1. That organisms are present in the blood stream, but of a type which defies our present methods of culture.
2. That the bacteria, though massed on the cardiac vegetations, are not circulating in the blood stream.
3. That the vegetations, and the blood stream also, have become bacteria-free.

In support of the two latter suggestions proof of a definite character may be quoted, certain cases having been recorded in which a completely sterile blood stream has been associated with endocardial lesions demonstrated *post mortem* to be teeming with bacteria; in other cases with negative blood cultures examination of the crushed vegetations entirely fails to reveal the presence of bacteria. The whole subject of blood cultivation in subacute bacterial endocarditis is undoubtedly important, and needs further investigation; our present state of knowledge, however, enables us to state quite positively that, for purposes of diagnosis, a positive blood culture is certainly not essential.

With regard to prognosis, we have unfortunately grounds for extreme precision: the disease is invariably fatal; three to twelve months may be looked upon as an average period, though the patient may drag on slightly longer in some instances. The progress of the disease is relentless and rapid; infective emboli are responsible for widespread and lasting lesions, and incidentally cause a large part of the suffering which these patients undergo. The cause of death is cerebral embolism, or hæmorrhage, uræmia, progressive anaemia, or intercurrent pneumonia.

The abbreviated notes of two patients recently admitted to this hospital will illustrate, from the clinical point of view, some of the features which characterize the progress of the disease.

CASE I.

G. W., aged 36, pensioner. Admitted September 14th, 1920; died November 7th, 1920.

Past History.—Negative except for trench fever in 1917. The serum test was negative. Onset of symptoms June, 1920: Dyspnoea, palpitation, pain under heart with exertion, slight cough; no hæmoptysis; loss of weight.

On admission (September 14th) the physical signs were pallor, clubbing of fingers, enlargement of spleen and liver, oral sepsis; heart enlarged; free aortic reflux; lungs engorged.

Progress.—Patient was in hospital three weeks, and, during this period, the condition became steadily worse; fever of an intermittent character persisted, petechial hæmorrhages were observed from time to time; sweats, rigors, and all the usual concomitants of septicaemia, complicated the final stages, and death took place on November 7th, barely five months after the onset of the initial symptoms.

CASE II.

S. B., aged 26, pensioner. Admitted September 1st, 1920; died September 25th, 1920.

Past History.—Negative. Discharged from the army March, 1917, for gunshot wound, face and neck. Serum test negative.

Onset of Symptoms.—May, 1920, palpitation after exertion, shortness of breath, vertigo, and fainting attacks.

Physical Signs on Admission (September 1st, 1920).—Pallor, anaemia, and poor nutrition; fingers clubbed, heart enlarged, free aortic regurgitation, vesicle's thickened, pulse collapsing in quality; liver and spleen enlarged and tender; petechial rash on neck and upper thoracic region; urine, heavy cloud of albumin and blood cells numerous.

Death from cerebral embolism on September 25th, five months after the first onset of the symptoms of the disease.

The *post-mortem* appearances in patients who have died of subacute bacterial endocarditis bear ample witness to the widespread nature of the disease. The heart is enlarged in most instances; the endocardium and valves are the seat of gross changes in the shape of extensive vegetations, which vary very considerably in appearance and consistency; the older lesions are usually firm, greyish, and calcareous, the most recent reddish yellow and extremely friable.

The valves involved are the mitral and the aortic, the latter more frequently than the former; in the majority of instances, however, the infective process spreads from the primary seat of infection, both to the adjacent endocardial wall and to the neighbouring valve; under these circumstances one notices that the oldest infection is the most extensive. It is important to observe that the right side of the heart is never involved, furthermore that the endo-

carditic process is of a purely vegetative character, ulcerative lesions playing no part in the condition.

A large number of conditions found *post mortem* elsewhere than in the heart might be mentioned; they depend in every instance upon embolic processes which may very obviously affect the arterial channels in any part of their course, and determine the production of visceral infarcts or hæmorrhages, mycotic aneurysms, etc.

Treatment.

Treatment should follow the broad lines adopted for any form of septicaemia: rest in bed should be absolute, the diet should be light and easily digestible; the action of the bowels must be free; drugs are of little value, though some temporary benefit may follow the prescription of tonics such as iron, arsenic, and quinine. Strychnine, by reason of its effect on the vasomotor centre, and digitalis, may be employed for symptomatic reasons and will sometimes assist in tiding over critical periods.

Intravenous injections of collargol and other metallic and antiseptic substances have been tried without success, no useful purpose therefore can be served by advising treatment of this nature.

Vaccines should be given a trial in all cases, but, in the experience of most observers, their remedial effect on the disease, in its fully developed stage, must be considered to be small.

The whole subject of treatment in this disease forces upon us the conclusion that subacute bacterial endocarditis, in the stage which permits diagnosis by gross physical signs, is an incurable malady. This being so, our duty becomes clearly defined: we must endeavour to recognize the initial stage of the disease, the early evidence that fresh infection has developed upon some old and quiescent lesion, the origin of the infective process, the factors which permit of its spread, the influence of a lowered tissue resistance, etc., for we know full well that, until we possess reliable data concerning the preliminary phases, our chances of lessening the mortality of this dread disease are wholly insignificant.

AN OPERATION FOR THE RADICAL CURE OF PRE-MASSETERIC FISTULÆ OF STENSON'S DUCT.

BY

GILBERT CHUBB, D.Sc., M.B., F.R.C.S.,

SURGEON, THROAT HOSPITAL, GOLDEN SQUARE AND PLASTIC SURGEON, QUEEN'S HOSPITAL FOR FACIAL INJURIES, SIDCUP.

THE ideal treatment for this condition is the restoration of the continuity of the duct (Nicoladoni). This, however, must always be difficult, and in any but recent cases must be impossible. An alternative method is to dissect out the duct, sever it from the fistula, and turn it into the mouth (Languebeck, also Riberi).^{*} As the original cause of the fistula usually produces considerable local scarring, this also is an operation that can only occasionally be successful. A large group of operations aim at the formation of an internal fistula, either by means of a ligature causing sloughing of the tissues between the duct and the mouth cavity (Deguise and P. Gould), or by means of a small tube passed through from the fistula into the mouth (Kaufmann's modification of Desconit's operation). All these methods are tedious and at the best uncertain. If these fail it is recommended either to ligature the duct, admittedly entailing the risk of abscess formation in the gland,[†] or to dissect and remove as much of the gland as possible without damage to the facial nerve. This method admittedly produces disfigurement, but is regarded as preferable to a persistent salivary fistula.

The number and varied character of the methods described for the treatment of this condition, and the drastic

* As an alternative to this method, when a considerable portion of the duct is destroyed, or much fibrous tissue is present, Du Jardin and Guiliers (*Ann. Chir. et Fac. de Chir.*, October, 1920) incise in the direction of the duct and dissect up both this and the masseteric promargination of the gland, which is then passed between the masseter muscle and the mandible, and stitched into the opening in the mucous membrane of the oral cavity.

† Morestin (*Bull. Aut. Men de Chir.*, Paris, 1917; Abstract S.G.C., 1917) makes a rule to dissect out and ligature the duct, the gland subsequently degenerating. This author has done 32 cases since 1915 by this method.

nature of some of them, is a sufficient indication of their uncertain value, and has induced me to publish the operation now described. Its advantages are great simplicity and, as far as I have practised it, reliability; while it permits of the complete removal of the fistula and surrounding scar tissue from the cheek with primary union of the remaining linear incision at one operation.

I have performed this operation in three consecutive cases.¹ In two the fistula was due to a gunshot wound in the malar region, and in one it followed the external rupture of an alveolar abscess. In each case the fistula was situated immediately in front of the anterior border of the masseter, and had been in existence for over a year. In one case a course of several months' treatment with the hard x-ray tube had failed to effect any improvement, and in another the fistula had previously been dissected out and the cheek closed by a plastic operation, without alleviating the condition.

The Operation.

Two horizontal incisions, about a quarter of an inch apart, are made, the one above and the other below the fistula.

FIG. 1.—Showing the incisions. A probe has been inserted into the fistula. The triangular areas of skin on either side of the area bearing the opening are discarded.

Two short vertical incisions serve to isolate a small button of skin bearing the fistulous opening. The posterior of these incisions is cautiously deepened, a probe being meanwhile retained in the duct lest the latter should be too closely encroached upon (Figs. 1 and 2). The anterior vertical incision is deepened at once until it enters the mouth immediately below the reflection of the mucous membrane opposite the upper molar teeth. In one case this area of the cheek was adherent to the alveolar border owing to scarring following the injury, and was mobilized by means of an epithelial inlay some weeks prior to the operation. The probe is now withdrawn, and small cat-gut mattress sutures inserted in the anterior and posterior lips of the skin button, and drawn through the wound into the mouth. Similar mattress stitches are inserted in the lips of the opening of the buccal mucous membrane, and these are now

FIG. 2.—The island of skin bearing the fistulous opening in course of mobilization. Deepening the posterior incision, with probe in position in the duct.

drawn through the wound into the mouth. Similar mattress stitches are inserted in the lips of the opening of the buccal mucous membrane, and these are now

FIG. 3.—Semi-diagrammatic horizontal sections showing: a, The condition of duct and fistula prior to operation; A and B, position of incisions. b, The mobilized area of skin bearing the fistulous opening, and containing the salivary duct in its pedicle; A and B, lips of opening, and containing the mobilized skin area; c and d, lips of the opening through the mucous membrane. c, The mobilized skin area seen in b has been inverted, and its edges sewn to those of the opening in the mucous membrane. The letters A, B, C, D have the same significance as in b.

tied together within the mouth. The original anterior edge of the skin button is stitched to the posterior lip of the opening in the mucous membrane, while the posterior edge of the latter is tied to the anterior lip.

(Fig. 3, a, b, c, shows diagrammatically the successive stages in this process.) No attempt is made to mobilize the skin button sufficiently to allow of its complete reversion. If it is turned over to face forwards and slightly inwards, the elasticity and loose attachment of the oral mucous membrane will allow of the latter being drawn up to the button, the post-operative appearance in the mouth being that of a conical recess of mucous membrane; passing backwards and outwards to the fistulous opening. The lips of the original incisions are now very slightly undercut and brought together, thus covering the reversed surface of the skin button bearing the fistulous opening.

In one of the three cases the tip of a defective probe remained in the duct, and was subsequently discharged through the operation wound. This has resulted in a slight external leakage, which, however, does not amount to a complete drop during a meal. In the other two cases healing was by first intention, and the wound has remained dry since the operation, now more than two years ago. In all three cases there is now a free and normal discharge of the parotid secretion into the mouth.

ADRENALIN IN RESUSCITATION FROM APPARENT DEATH.

BY

CRANSTON WALKER, M.D., B.Sc.,
HONORARY PHYSICIAN, GUEST HOSPITAL, DUDLEY, ETC.

ANAESTHESIA, asphyxia, the passage of a powerful electric current, violent emotion, and violent sensory stimulation may place the body in a state which resembles that of a clock which has been stopped, but not permanently damaged; if the machinery can be restarted it will continue to run automatically. Relatively simple means will often suffice to set things in motion again, as a mere shake will serve to start a clock. Sometimes it appears as though a more accurately fitting stimulus were required, like a swing in time with that of the pendulum.

Mr. Welby Fisher, in a very interesting paper,¹ advocated cardiac massage applied through an epigastric incision. He makes no reference to the use of adrenalin. The following notes of a limited experience may be of interest.

Adrenalin applied to the heart muscle acts on the sympathetic neuro-muscular junction, and very greatly increases both the excitability of the tissue and the energy output of the muscular contractions. In some twenty cases of death from various causes, when all signs of life had ceased for several minutes, I have injected a minim or two of 1 in 1,000 adrenalin chloride directly into the heart muscle. A fine needle was passed through the fifth left intercostal space, just mesial to the lung resonance; the point was directed slightly inwards and upwards, and could be felt to enter the apex of the heart; when firmly imbedded in the muscle the injection was made. Several of these needle tracks were examined *post mortem*, and in no case did it appear that any drawback would have ensued had the patient survived.

In most of the cases death had occurred as the result of long established disease, and adrenalin was neither expected nor observed to have any effect (a fact not without interest). In the following three cases circumstances were more favourable.

CASE I.

A splendidly built young man had received a powerful electric shock while fitting an electric lift, and all appearance of life had instantly ceased. When seen by me it is estimated that about twenty minutes had elapsed; there were no signs of circulation, the upper parts of the body were pale, the lower were dusky, showing that the blood distribution was determined by gravity; the skin was already cool. Artificial respiration was applied, adrenalin injected into the heart muscle, the needle shaken *in situ*, the heart was massaged, but without abdominal incision, and was stimulated faradically. There was no response.

CASE II.

A child of 11 months during a circumcision under chloroform had stopped breathing, and became pale and flaccid; the pupils were dilated, no pulse could be felt, and no heart sounds could be heard. Artificial respiration was started, and the heart was massaged by pressing the fingers under the costal margin; in this case the heart could be felt, and almost gripped between the fingers. There was no response, and the body was cooling perceptibly. Adrenalin was injected into the heart muscle, immediately the heart started beating; shortly after respiration recommenced, and in a few minutes the child appeared normal. The time was not accurately observed, but it is estimated that at least four minutes had elapsed between the stoppage of the

pulse and the injection of adrenalin. The anaesthetist's estimate is considerably greater. The child was seen at intervals for three or four weeks; not the slightest ill consequence was detected.

CASE III.

A woman of 30, with emphyema, had just had an exploring needle passed into an intercostal space. Suddenly she became limp and pale, she murmured a word or two, but the sound diminished into silence. She dropped back, apparently dead. The muscles were quite flaccid and motionless, no pulse could be felt nor heart movement heard; jaw and eyes were in the cadaveric position. Artificial respiration was commenced, and adrenalin was sent for. Suddenly the pulse returned, beating strongly under the fingers, the patient flinched, and a few minutes later she was sitting up and talking. She had passed through a Stokes Adams attack, subsequently repeated. Possibly more detached observation would have detected an auricular pulsation in the jugular veins. Had the adrenalin arrived half a minute sooner a striking success might erroneously have been ascribed to it.

Although Case III shows the need for caution in interpreting results, Case II suggests that injection of adrenalin into the heart muscle may restart it when other means fail.

Conceivably the needle might be pushed on into the cavity of the left ventricle and Ringer's solution containing adrenalin might be run in under pressure through a tube and funnel; on passing through the coronary arteries the adrenalin would be brought much more intimately into contact with the heart muscle, and would reach the more excitable sinus node and auriculo-ventricular bundle. The flow of Ringer's solution, preferably oxygenated, would also supply a temporary artificial circulation. Reports on wounds of the heart suggest that the risks of passing a fine needle through the apex of the heart are small compared with those of the desperate condition in which such means would be used. The method seems sufficiently promising to invite preliminary experiments on animals.

COMPLEMENT FIXATION TESTS IN THE DIAGNOSIS OF TUBERCULOUS INFECTIONS.

(A Preliminary Note.)

One of the writers began to study complement fixation tests in the diagnosis of tuberculous infections in the autumn of 1919. He was joined by his colleague later in the year. Our work is not yet finished, but it is hoped that the results will be advanced sufficiently for publication within a few months.

Complement fixation tests in tuberculosis have been studied by numerous workers since 1901. Varying results have been obtained, attributable to differences in technique and the characters of the antigens used.

We have attempted (1) to test the relative value of types of some of the chief antigens which have been used in the past; (2) to devise a reliable technique. We have tested four antigens up to the present time:

- (a) A saline emulsion of living tubercle bacilli.
- (b) An alcoholic extract as proposed by Craig.
- (c) An alcoholic extract as used by Dudgeon.
- (d) An antigen prepared by Wang and Crockett's method.

We find, on the whole, that the antigen of Wang and Crockett is reliable, and probably the best one that has been used to any extent up to the present time. With this antigen, and using a technique modelled on the ordinary Wassermann method, we have tested cerebro spinal fluid and serum from cases of tuberculosis, and from non-tuberculous cases, including normal serums and serums from patients suffering from various diseases. We obtained 61 positive results in 85 cases of definite active tuberculosis, and negative results in 50 non-tuberculous cases. We also obtained some positive reactions with serums giving a strongly positive Wassermann reaction, as previously found by Wang and Crockett. Our work is now being applied mainly to the investigation of tuberculous disease in children.

LETHARGIC ENCEPHALITIS.

As it has been my fortune to see no less than seven cases of this disease in the past fortnight, though previously for some months I had met with no fresh case, it would appear that a temporary recrudescence of intensity of the epidemic is occurring. The virulence of infection also has not notably lessened, two of these cases having already died.

As with all diseases named after a prominent symptom, lethargy is not an invariable occurrence in this form of encephalitis, and one feature that has been prominent in at least two of my recent cases, namely, quiet delirium and delusions, may lead to a mistaken diagnosis of insanity; indeed, one of my patients was brought to me by his friends from a distant suburb because the doctor in attendance said it was a mental case and should be sent to an institution. Another I have just seen has been treated for nine weeks for nervous breakdown, as he complains that his brain is not right. He has been observed frequently talking to himself about business troubles, worried much about his bladder, unnecessarily so according to his wife, and one day said to his doctor that he had 37s. 6d. in his bladder which he wanted to pass! He showed no drowsiness and was allowed to go about as usual, but the clue to recognition of the encephalitis lay in his mask like facies resembling paralysis agitans, with marked tremor of one hand, small irregular pupils reacting poorly to light, and a pulse of 90.

Many patients complain early of blurring of vision, scarcely diplopia, and then nystagmus is usually present, perhaps most intense on looking downwards. Pyrexia of 101° F. or more and a rapid pulse are bad signs, the prognosis as regards life being almost in proportion to the degree of tachycardia. Quite a number of cases show no ptosis or drowsiness, and with the absence of ocular symptoms the recognition of this disease may be overlooked unless its present prevalence be constantly kept in mind. In others muscular twitchings are prominent, and sometimes headache, though usually no pain in the head is complained of.

It is important that cases of this disease should be kept at rest and free from worry, using sedatives and hypnotics, such as ammonium bromide and chloralamide if required, in order to limit the liability of permanent cerebral lesions occurring, which have been only too frequent. Many such cannot be avoided, one of the commonest being a permanent mask like rigidity and perhaps tremor, resembling paralysis agitans closely, and due to lesions in the lenticular nucleus, as in that disease.

London, W.

WILFRED HARRIS, M.D., F.R.C.P.

A CASE OF CARDIAC MASSAGE.

AFTER reading Mr. Fisher's article on resuscitation in death under anaesthesia in the JOURNAL of November 6th, 1920, I think it may be interesting to publish notes on the following case; though the treatment was not finally successful, yet the response was so marked as to emphasize the importance of the method.

The patient was a weak thin man of 45 to 50. On August 21st, 1920, the operation of gastro enterostomy was being performed by Mr. I. O. Lasbrey for continual pain and vomiting. It was largely completed when the patient stopped breathing. Artificial respiration was performed and breathing very soon started again, but the pulse was very weak. The operation was continued, but in a few minutes breathing stopped again, and the pulse could not be felt. Artificial respiration, strychnine, ether under the skin, hot cloths to the epigastrium were all tried without avail. The gloved hand was inserted in the abdomen through the operation incision and an attempt made to massage the heart through the diaphragm, but the heart could not be felt at all. Finally, after half an hour, during which time there had been no voluntary breathing and no pulse or audible heart sounds, the case appeared quite hopeless. Then direct massage of the heart was tried. I cut through the anterior left fibres of the diaphragm and passed my gloved hand, by means of the abdominal incision, through into the chest cavity. I found the heart small, flabby, and empty, and quite without movement. I continued to massage it for some time, and meanwhile,

the heart began to respond, inasmuch as it became firmer and larger, and on squeezing it empty it automatically filled again. Massage was continued. Shortly after, on ceasing the massage for a brief period, a very small beat, feeling almost like a tremor, continued, but only for a very short time. Pituitrin extract, 1 c.cm., was given, and soon after, on ceasing the artificial respiration, the patient took one respiration himself,

but did not continue. Again later the heart continued to go for a brief time alone and the patient breathed again. Then he breathed twice in succession, later three times, and so on till he twice breathed automatically nine times consecutively, but did not continue. Also the heart would not keep going for long if the massage were suspended. About a pint and a half of normal saline was injected into a vein in the arm and more pituitrin extract given, but the breathing would not start again. The heart gradually got weaker. It still responded to massage, but would only give one or two beats when left alone, till finally, nearly two hours after breathing first stopped, response failed and the case was given up.

We may note that the heart had given no sign of beating for about half an hour when direct massage was tried. It could not be grasped or moved at all through the diaphragm because it was small, empty, and flabby, and lying against the back of the chest wall. Massage was continued for over an hour, and up to nearly an hour after commencing direct massage there was irregular and non-continuous automatic heart-beating and unaided respiration. This case might have been hopeful had direct massage been employed earlier. It would appear wise in every case of collapse under anaesthesia to employ cardiac massage as soon as it is ascertained that the heart has ceased to beat.

Old Cairo, Egypt.

Reports of Societies.

SURGERY OF THE ELBOW.

At a meeting, held on November 26th, 1920, of the Surgical Section of the Royal Academy of Medicine in Ireland, with Sir W. I. DE C. WHEELER in the chair, Mr. R. ARKINSON STONEY read a paper on modern surgery of the elbow, and showed three cases of excision of the elbow operated on from ten months to ten weeks previously for ankylosis following gunshot wound. A fourth case was shown of operation for flail elbow, also succeeding gunshot wound. In all cases the result was an arm with good movement of the elbow and fair stability. Owing to the short interval which had elapsed since some of the operations, further considerable improvement might confidently be expected. As a result of the Great War, the speaker said, the surgery of the elbow had retrogressed by forty years. Before the war an ankylosed elbow was looked upon as a success, and excision for it was banned. The change of surgical teaching was largely caused by the bad results obtained by excision of the elbow in the early stages of the war, and this again was the result of the employment by unsuitable men and in unsuitable cases of the operation of primary excision—an operation which was probably never justifiable except as a life-saving or arm-saving device employed by the inexperienced. The teaching was now becoming crystallized that excision was unsuitable for gunshot wounds of the elbow, and that the ideal result was an ankylosed joint. This it appeared was largely due to the application of the principle of reducing the standard to the lowest capacity—an attempt to make rules to fit all cases. A good elbow with free movement and moderate stability was possible of attainment in most cases of ankylosed joint, and in some cases of flail elbow. Each case of ankylosed or flail elbow should be carefully considered with regard to (1) the present condition, and the handicap caused to the patient's work; (2) the result that might be expected from operation, especially with regard to the relative movement and stability of the new joint; (3) the consequent increase in the man's capacity or usefulness at his old or some new occupation. The position should then be fairly explained to the patient, and he should be allowed to decide for or against operation.

The main points in excision were: Vertical division of the triceps and its insertion into the periosteum and deep fascia of the forearm; limited removal of bone in the forearm; careful suture of the wound in layers; drainage; early electrical treatment and massage. The main points in operating for flail elbow were: Division of tissues between bones in a vertical direction from behind until the fibres of the brachialis anticus were reached; adjustment of bone ends, which should be united, preferably by several strands of silkworm gut; suture in layers of the

tissues behind the bones; no drainage; avoidance of early weight or strain on arm.

Sir WILLIAM WHEELER said that while individual cases should be treated on their merits, it was his general practice to mobilize ankylosed elbows in officers, and in men to secure fixation at an open angle, especially in the left elbow-joint. A certain degree of lateral mobility was inevitable after resection, and, as a rule, the security of a fixed joint was better for manual work. Mr. H. STOKES spoke in favour of fixation, and described the originally desperate condition of one of Mr. Stoney's patients whom he had seen in France with streptococcal septicaemia. Mr. ADAMS A. MCCONNELL maintained that the question of fixation or mobilization should be decided by the employment which the patient wished to follow. Mr. DOOLIN referred to the dangers of lighting up latent infection in wounded joints, particularly in the case of tetanus. He had been accustomed to use the Kocher incision instead of the vertical.

Mr. STONEY, in reply, said that no rule could be framed for treating lesions of the elbow. Each case should be given the opportunity of the treatment best suited to its requirements. He had never had a case of gunshot injury where tetanus had been lighted up by operation; he used a dilute bipp as a prophylactic against latent sepsis.

PATHOLOGY OF INFLUENZA.

At a meeting, held on December 2nd, 1920, of the Pathological Section of the Liverpool Medical Institution, the President, Dr. J. E. GEMMELL, being in the chair, Dr. J. G. ADAMI, Vice-Chancellor of Liverpool University, read a paper entitled "The pathology of influenza: an attempt to find a common lesion for the successive stages of pre-pandemic purulent bronchitis, pandemic pneumonia, and the haemorrhagic pulmonary oedema characteristic of the late pandemic of influenza, and to distinguish those lesions due to the primary causative agent from those due to the secondary invaders."

Dr. Adami first referred to the generally accepted view that the influenza epidemic started in May of 1918, and was followed by a much more serious epidemic in the autumn of that year. He did not, however, think that this view was correct, for early in 1916 and the spring of 1917 Hammond, Rolland, and Shaw had described a series of cases of purulent bronchitis in what was now known to have been the Etaples area. These cases were characterized by a peribronchitis, a destruction of the lining bronchial epithelium, and a bronchitic and bronchiolitic purulent discharge, all of which were associated with the presence of both the influenza organism and the pneumococcus. It was curious to note that in the same year (1917) an exactly similar epidemic was noted in the Aldershot area by Abrahams. Further, in that year American bacteriologists noted a very fatal form of pneumonia following measles. MacCallum showed that the morbid anatomy of the respiratory tract was that of an interstitial pneumonia, an exudate that was not excessively cellular, a destruction of the epithelium of the bronchi, and a microscopic appearance of the bronchioles entirely distinctive of that found in the French and

This investigator found, however, that the chief organisms in this series were a haemolytic streptococcus and the pneumococcus; the influenza organism was only noted a few times. Then came the great epidemics of 1918. Dr. Adami showed that in the reports from France, Macedonia, Italy, India, and America, it was possible to trace a morbid histology and bacteriology common to all. In all areas the disease was ushered in with congestion and suppuration of the upper nasal respiratory tract, and in those regions where those parts had been bacteriologically examined reports invariably showed that the influenza organism had been recovered. Further, a tracheitis limited to the lower third of the trachea was perhaps the greatest common histological factor. The speaker felt sure that whatever might have been the changes due to other bacteria, the influenza organism of Pfeiffer, if not the *causa causans*, was always associated with the disease. In the autumn, however, it was obvious that the virulence of the organism had been raised to an inordinate degree, and Dr. Adami suggested that the absence of pus, the haemorrhagic oedema, and the marked lymphatic dilatation

might be explained by negative chemiotaxis. In this connexion reference was made to the classical experiments of Metchnikoff on mild and virulent anthrax organisms. After demonstrating the means whereby the lungs were protected from micro organisms by the obliquity of the nasopharynx and by the ciliated epithelium, Dr. Adams showed how in influenza this protective device broke down.

The discussion was adjourned until the next pathological meeting.

CLINICAL CARDIOLOGY.

A MEETING of the Devon and Exeter Medical-Chirurgical Society was held at the Royal Devon and Exeter Hospital on December 16th, 1920. In the absence of Mr. B. Dyball, the President, the chair was taken by Colonel RANSOM PICKARD, C.B., C.M.G.

Dr. W. GORDON read a paper on the practical gains of clinical cardiology since 1900 (printed in the *BRITISH MEDICAL JOURNAL* of January 1st). In the discussion which followed, Dr. B. KELLY commented upon the comparative rarity of massive oedema as a complication in cases of cardiac disease occurring in the Exeter area. He had also noted that when oedema did occur it was a late manifestation in the case, and where his experience had taught him to expect no improvement. He asked Dr. Gordon if he could give any explanation for this local variation. Dr. R. V. SOLLY, in alluding to the subject of malignant endocarditis, mentioned that short streptococci had been found in the majority of his cases, and that vaccine treatment had not so far proved to be of any benefit.

Mr. NORMAN LOCK gave an account of two cases where manipulation of the heart had been undertaken for the treatment of profound shock, and he also narrated the case of a man from whom he had removed shrapnel embedded in the anterior border of the heart. Prior to operation the man showed high grade cardiac inefficiency, but he had made a good recovery, and was now able to earn his living at a moderately light occupation. Dr. F. A. ROPER considered that "irritable heart" must not too readily be assigned to neurasthenia. As regards heart hurry he had frequently noted a high blood pressure in such cases, and he had often had reason to suspect that the condition might lead to actual arterio-sclerosis. He was of opinion that clinical instruments, such as the electro-cardiogram, although not directly concerned with treatment, were a powerful attribute to diagnosis.

Dr. J. D. HARRIS spoke of his personal experience as to the value of digitalis in two cases of auricular fibrillation. He referred also to the difference in the long axis of the heart as shown by x-rays in various subjects. With regard to treatment in streptococcal infection, he discussed the possibility of x-rays being able to reach the endocardium, having regard to the short distance from the surface. Dr. H. E. WHITE commented upon the irregular heart so often noted after measles in children, and he asked for an explanation of a murmur audible in the axilla but not at the apex. Dr. T. R. WILKINSON discussed the value of the cardiogram in demonstrating myocardial changes. Mr. WILLIAM SMITH paid tribute to the benefit derived from the employment of atropine in cases of enteric fever occurring amongst the troops in France. Slow action of the heart—an early symptom—had been considered an indication for giving the drug.

Dr. G. L. THORNTON referred to the comparative decrease in the number of cases with a diagnosis of disordered action of the heart appearing before pensions boards during the past twelve months. The majority had been classified into their respective cadres, quite a large number being symptomatic or sequelae of malaria or dysentery, and responding to the treatment given for the parent disease. Others had been referred to the neurological clinics as entirely of nervous origin, whilst most conspicuous was the high figure of those who had been proved to be suffering from pulmonary tuberculosis, the dyspnoea and poor cardiac response apparently being but an early symptom of that disease. A small minority remained where the onset of the cardiac disability could be referred to strain during service.

Dr. A. H. WILKES referred to the cardiac condition found amongst cases attending the tropical diseases clinic, and

emphasized the importance of sub-classification, if the term "D.A.H." was to be used at all. Colonel RANSOM PICKARD, speaking from his experience as the A.D.M.S. of a Division, had noted the loose employment of the classification "D.A.H.," and of the amount of correction in diagnosis which had been found necessary when so-called cardiac cases were examined at medical boards.

Dr. W. GORDON, in reply, stated that in his opinion instrumental methods were impracticable for general use, and that they were of physiological rather than of clinical utility. With regard to Dr. White's question he had frequently noted a respiratory murmur in the axilla. He had made observations similar to those of Dr. Kelly, and attributed the cause to a mild climate, which made complications such as bronchitis or nephritis less frequent. As regards treatment in malignant endocarditis, he mentioned improvement after injections of antistreptococcal serum, and more recently of eusol intravenously. He hoped that the connexion between "D.A.H." and early tuberculosis would be given publicity. Referring to remarks made by Dr. Harris, he stated that the axis of the heart was daily receiving more attention. He had had no personal experience of atropine in enteric fever.

Reviews.

DR. CREIGHTON'S CONCLUSIONS ON CANCER.

IN his recent work *Some Conclusions on Cancer* Dr. CHARLES CREIGHTON brings forward the result of work, published and unpublished, extending over nearly fifty years. The problem of cancer has thus been critically studied by him for an exceptional period and after such prolonged investigation his views demand respectful consideration, even though they may run counter to generally accepted opinion, and are not very easy to grasp. A study of chorion epithelioma, which provides special data supporting his deductions, was recently undertaken at the London Hospital, and ample opportunities for investigating mouse cancer have been utilized. The object of this volume is avowedly not controversial, critical, or negative, but to put forward positive conclusions based on original observations and argued at first hand. After an introduction, which summarizes the argument, the first part, illustrating the principles, deals at some length with chorion epithelioma, mouse cancer, and malignant tumours of the eyeball, the second part describes cancer in its common sites—namely, the skin, the alimentary canal, breast, and uterus; the last chapter sums up the author's views on causation, and there is an interesting appendix on the history of endothelioma.

Dr. Creighton insists that cancer is not due to one cause only and that the search for a unit of causation will lead to disappointment, for in every cancer there are various co-operating factors, of which one may be predominant in one form or locality of the disease, another in a different one. He argues that the commonly accepted view that cancer is due to a continuous overgrowth of pre-existing epithelium is erroneous, and that recent investigators of chorion epithelioma and mouse cancer have missed a great opportunity because they have been dominated by this conception. Consideration of chorion epithelioma, mouse cancer, glioma of the retina, and melanoma of the choroid leads him to the conclusion that the blood is the important factor, but he points out that discrimination is necessary in translating the old language of cancer as a blood disease into the more exact technical terms of modern research. The blood, he holds, is implicated in various ways to the same end, in chorion epithelioma it is acted upon by a ferment diffused from the foetal epithelial cells, and the blood thus altered provides the food for the new growth, in mouse cancer a dyscrasic state of the blood due to interbreeding is assumed, and to the two forms of intra-ocular malignant disease other explanations apply. The blood and the blood vessels are inseparable, and when in disease the cells of a part feed on the blood, the cells most concerned are in the walls and adnexa of the blood vessels. Malignancy always means that the cells of an organ or tissue take to feeding on the substance of the red blood corpuscles instead

¹ *Some Conclusions on Cancer*. By Charles Creighton. M.D. London: Williams and Morgate. 1920. (Rox. 8vo pp. 378, 115 figures. 42s. net.)

of metabolizing it, storing it up, or passing it on; and a disproportionate nucleus is regarded as a sure index of a structure built up from ferment-reduced blood. Thus a cancer is a blood-built structure composed of blood vessels and gland tissue. The analogy with the physiological blood-built structure of the placenta, on which Dr. Creighton has written much, would be more complete if syncytium were more generally present in morbid growths than is now recognized, and this from his own observations he believes to be the case.

TEXTBOOKS OF HYGIENE.

A VOLUME consisting of over 400 pages, even dealing with so wide a subject as public health, can hardly be included among those termed cram books, and there are many other reasons why *Hygiene*,² by Dr. JAMESON and Mr. MARCHANT, should not be so categorized. The authors describe it as an attempt to epitomize the views of accepted authorities and the most recent work in the huge subject of hygiene. We may state at once that they have not been unsuccessful in that endeavour. They have produced a textbook well planned, easy of reference, and reliable. Far more than the surface of the subject has been scratched, but the student is not taken into such depths as to obscure his vision for essentials. Whatever other textbooks he may have studied, he will almost certainly find in this one either something entirely new or a specific subject put forward in a new form. The arrangement of the work follows very much on the lines of older textbooks. The earlier chapters deal with water supplies, the removal and treatment of waste matters, ventilation and heating, soils and building construction, and with food supplies. These are followed by chapters on infant mortality, child welfare, school hygiene, prevention of disease, industrial diseases, vital statistics, sanitary law, meteorology, and some notes on chemistry. The section dealing with industrial diseases, though covering only nine pages, gives evidence of much painstaking inquiry, and will be helpful for examination purposes, but it is capable of considerable extension. On page 169 reference is made to the influence upon the incidence of tuberculosis of back-to-back houses, and mention is made of the Salford investigations. There have, however, been much more recent inquiries than that at Salford, and with more convincing results. The statement on page 261 that the appointment of a medical officer of health to an urban or a rural district cannot be terminated without the consent of the Ministry of Health is not yet correct. The full title of the Order under which these officers are appointed is "The Sanitary Officers (outside London) Order, 1910." The proof reading of this work has been remarkably well done, though on page 302 the Infectious Disease Notification Act is described as the Infectious Diseases Act. Such minor slips will no doubt be remedied in the future editions which will deservedly be called for.

One of the earliest textbooks included in Lewis's Practical Series was that on *Public Health Laboratory Work*,³ by Professor HENRY KENWOOD. The seventh edition is concerned only with the chemical branch of the subject. Part VII, which appeared in former editions and referred to microbiology, is omitted; the subject is to be dealt with in a separate volume from the pen of Professor Sheridan Delépine. The general arrangement of previous editions has been followed in this, the subject being dealt with under the headings of the examination of water, sewage and sewage effluents, soil, air, food and disinfectants. There is ample evidence of drastic revision of former editions, and there has been a fearless combing out of superfluous paragraphs and of matter which research in recent years has rendered out of date or unreliable. For example, in 1908 Professor Kenwood, when writing of the presence of zinc in water supplies, stated that a trace of this metal (not exceeding one-tenth of a grain to the gallon) might perhaps be allowed, but he now states that he has found up to one grain per gallon in

many waters which have been in contact with galvanized iron and used for many years in public institutions without any evidence of harm. His opinion now is that one-third of a grain per gallon should not be exceeded. It would have been helpful if the author had expressed his own opinion more freely on the question of dirt in milk. It has been suggested, he writes, that as a general rule the recoverable dirt should not be allowed to exceed two parts per 100,000 by weight. As a rough household test half a pint of milk placed in an ordinary tumbler should not throw a visible sediment in two hours. He admits, however, that, as dirt may be partially removed by trade filtration, leaving behind the harmful bacteria, the only satisfactory standards are those based upon bacterial counts. In the section on food examination he discusses at some length the question of poisoning by food. He is in agreement with present-day observers that ptomaines are not the cause of extensive outbreaks of meat poisoning, which are, he considers, commonly caused by the bacilli of the Gaertner group. The section on water examination has been subjected to most careful revision, and the concise and clearly expressed instructions for carrying out various processes have been made even more lucid and intelligible. For this reason alone, if merely as a time saver, medical officers of health and others engaged in public health laboratory work will find this book invaluable.

A MANUAL OF NEURASTHENIA.

IN *A Manual of Neurasthenia* by Dr. I. GEBIE COBB the general practitioner will find a thoroughly helpful and comprehensive account of a disorder which bulks largely in his daily work. The book is written on sound, practical lines. The symptom-complex of neurasthenia is clearly described; the etiological factors are discussed in detail; a full account is furnished of the various mental and physical symptoms and objective signs; the treatment is indicated under the headings of general hygiene, principles and details of diet, use of drugs, climate, psychotherapy, electricity, and other special methods; and the points of differentiation between neurasthenia and conditions for which it might be mistaken are indicated in schematic form.

Dr. Cobb regards neurasthenia as a definite clinical entity. He finds (p. 205) that "the cardinal symptoms and signs are so constantly associated that they form as certain a correlate as those of any well-recognized disease. The presence of undue fatigue, typical headaches, digestive disturbances, and sensory abnormalities points to the presence of the disorder." In regard to this vexed question, it may be said that the range of cases in which neurasthenia will be regarded as an adequate diagnosis will no doubt tend increasingly to diminish. Further research will probably make it clear that many cases of nervous exhaustion are symptomatic only, and the expression of definite and specific underlying causes. Since the disorder was first described the tendency has been all in this direction. Dr. Cobb would seem to have included as much and no more in his neurasthenic group than the facts warrant in the present state of our knowledge. Since the diagnosis of neurasthenia is often made to cover almost any type of nervous illness, he has very wisely made perfectly clear and definite what he includes under the concept of neurasthenia. He excludes many symptoms which the term originally included, such as obsessions, phobias, and anxiety, but he uses it in a wider sense than Freud by including the chronic form of nervous exhaustion occurring in middle age, as well as the restricted group in which auto-eroticism is the pathogenic factor. Since he adopts this wider conception of neurasthenia, Dr. Cobb naturally finds a number of factors instrumental in its production, and he devotes considerable attention to toxic and other causes of a physical nature. A full recognition of mental factors is given, and the view is expressed and developed at length that emotional influences cannot be limited to the sexual sphere, but that other instinctive trends have to be reckoned with in the production of nervous exhaustion. While we quite agree that conflict as a factor in the production of neurasthenia is certainly not confined to the sexual impulse, yet the

² *Hygiene*. Specially adapted for those studying for a Diploma in Public Health. By W. Wilson Jameson, M.D., Aberdeen, M.R.C.P., D.P.H., and F. T. Marchant, M.R.San.I. London: J. and A. Churchill. 1920. (Demy 8vo, pp. 404; 18 figures. 18s. net).

³ *Public Health Laboratory Work* (Chemistry). By Henry R. Kenwood, C.M.G., M.B., D.P.H., F.C.S. Seventh edition. London: H. K. Lewis and Co., Ltd. 1923. (Demy 8vo, pp. 451; 4 plates, 25 figures. 15s. net).

⁴ *A Manual of Neurasthenia (Nervous Exhaustion)*. By Ivo Gebie Cobb, M.D., M.R.C.S. London: Baillière, Tindall, and Cox. 1920. (Demy 8vo, pp. xvi+366. 12s. 6d. net).

important fact that neurasthenia in young people is often closely related to active auto-erotic tendencies is perhaps insufficiently stressed. The term "auto-eroticism" is hardly explained sufficiently to be helpful to the practitioner. It is not made clear that this term in relation to neurasthenia refers to onanistic tendencies which lead to fatigue symptoms through excessive expenditure of nervous energy. Though the question of mental conflict is also involved, the sexual etiology in neurasthenia would seem, in a sense, to be physical in character as contrasted with the purely psychogenic origin of the symptoms in the psychoneuroses. We venture to make this comment because we think more attention to this difficult subject in the section devoted to treatment would have been of practical value to the practitioner, as it is a question he has constantly to face in dealing with his young patients.

The chapters devoted to symptomatology are particularly clear and complete, and due emphasis is laid upon diagnostic points. The treatment also is described fully, and the value and limitations of the various therapeutic agents excellently discussed. The detailed instructions herein found contrast favourably with the either too vague or too specialized methods of approach which characterize much that is written on the neuroses. In a subject such as neurasthenia, which presents peculiar difficulties and which may be investigated from so many points of view, it is inevitable, and no doubt necessary, that certain causal factors should be over-emphasized by observers with specialized interests. Dr. Cobb has managed, however, to present a broad and impartial account of the disorder. In his preface he says: "The exclusive preference shown by many . . . for the hypothesis of physical origin on the one hand or of mental on the other, has made the task of steering between the Scylla of mind and the Charybdis of body a difficult one." The task is undoubtedly difficult, but in the present instance it may be regarded as having been successfully accomplished.

NOTES ON BOOKS.

The mere fact that a work devoted exclusively to the subject of impotence has survived five editions is—as its author points out in its preface—an indication that such a work was required. It is certainly true that the failure of sexual desire and sexual power may be the cause of a great amount of mental suffering, and that the subject is thereby endowed with considerable importance. The study of sexual impotence embraces such widely varied themes as psycho-analysis and endocrinology. Impotence may be a symptom of many different pathological conditions, and to arrive at a correct diagnosis demands considerable clinical acumen. Three-quarters of Dr. VECKI's work is devoted to a discussion of the various forms of impotence, and the final chapters deal with treatment. The great number of the methods of treatment that have been advocated by different authorities is an indication of their inefficiency. Yet, in the words of the author, "there is hardly any one of them that could be entirely dispensed with because there are cases in which one or the other may be of some use." Of the utility of retaining some of the methods described in this work we are sceptical. Even the enthusiasm of Dr. Vecki fails when describing some of the hundred and one therapeutic measures that have been advocated. For the moment the hope of the impotent would appear to be in the realm of endocrinology. In the concluding chapter is an interesting summary of present knowledge on the subject of the endocrine glands and their relation to the sexual function. The author has wisely confined himself to the task of supplying his reader with facts and has resisted the temptation to indulge in vague speculations.

A Dictionary of Scientific Terms by I. F. and W. D. HENDERSON, of the University of Bristol, contains about 10,000 definitions, including those of several hundred lately coined expressions, many of which have not hitherto found their way into a dictionary. In addition, it gives the pronunciation and definition of the terms used in biology, botany, zoology, anatomy, cytology, embryology, and physiology. The Greek words given in connexion

Sexual Impotence. By V. G. Vecki, M.D. Sixth edition, revised. Philadelphia and London: W. B. Saunders Co. 1920. (Demy 8vo, pp. 222, 16s. net.)

A Dictionary of Scientific Terms. By I. F. Henderson, M.A., and W. D. S. Henderson, M.A., B.Sc., Ph.D., F.R.S.E. Edinburgh: Oliver and Boyd, 1920. (Demy 8vo, pp. 320, 15s. net.)

with derivations have been transliterated, because, as the preface states, students of science and medicine are considered to be seldom acquainted with that language, and the transliteration of certain combinations of letters represents the sound rather than the exact letters of the original—for example, *branchia* appears as *brangchia*, and *korumbos* as *korymbos*. A superficial examination of the work gives an impression of its utility to medical students in their early years, and of the labour and care the compilers have devoted to this well-printed work. It does not include terms used solely in clinical medicine and surgery and in pathology.

PRESENTATION TO DR. J. A. MACDONALD.

The following further subscriptions have been received from November 29th to December 31st, 1920, in response to the appeal published in the *JOURNAL* of July 24th (p. 129), towards a presentation to Dr. J. A. Macdonald on the occasion of his retirement from the office of Chairman of Council of the British Medical Association which he had held for ten years. Subscriptions of any amount not exceeding five guineas should be made payable to "The Macdonald Presentation," and sent to the Medical Secretary, British Medical Association, 429, Strand, London, W.C.2.

OWING to the rise in the cost of printing and paper the subscription to the *Nederlandsche Tijdschrift voor Geneeskunde* for 1921 has been raised from Fl. 18 to Fl. 25.50.

PROFESSOR OTTO LANZ of Amsterdam, a native of Switzerland, has resigned his membership of the Société Internationale de Chirurgie as a protest against the exclusion of the surgeons of Central Europe.

DR. CARLIER, professor of clinical urology in Lille University and an authority on diseases of the prostate, has recently died.

IN the various German universities 85,000 students were enrolled last summer as compared with 55,000 in 1914. Of the total number 18,319 were medical students and 4,723 dental students, as compared with 16,048 and 976 respectively in 1914.

A SOCIETY entitled "Société Bruxelloise de laryngologie" has recently been formed at Brussels. Its meetings will be held monthly.

REFORM IN MEDICAL EDUCATION.

[FROM A CORRESPONDENT.]

(Continued from page 22.)

I.

REVISION OF THE MEDICAL CURRICULUM.

The replies from the schools as to education in preventive medicine seem to have had a great effect on the outlook of the Education Committee and the General Medical Council, for in a full report to the Council at the May session of 1920 it urged that the numerous considerations and recommendations submitted by the schools raised the whole question of revision of the medical curriculum apart from, and in addition to, the teaching of preventive medicine. This view was strengthened by the publication of Sir George Newman's "Notes on Medical Education in England," and the Edinburgh Pathological Club's "Enquiry into the Medical Curriculum."

It may be noted that the replies from the schools were in general very sympathetic in respect to the query by the Council concerning "teaching regarding the maintenance of health from birth onwards." It appears, indeed, that the organizations for child welfare developing all over the country are being in many cases linked up with the medical schools for the purpose of teaching to students the prevention of disease from infancy onwards. The Middlesex Hospital School writes that "in the case of diet and childhood considerable instruction is given in connexion with the infant welfare department, but we are fully alive to the fact that instruction on the prevention and arrest of disease might be amplified with considerable advantage." The University of Edinburgh replies that "opportunity for the study of infant nutrition and dietetics is furnished also by the Municipal Scheme of Child Welfare, and the students who attend are trained in the administration of the preventive clinics." University College Hospital School "wish to call attention to the fact that at this hospital there is a well-equipped maternity and child welfare centre in which the feeding and the health of infants and children is taught to the students." In connexion with St. Mary's Hospital School, the Paddington Green Children's Hospital "secures that the student shall have special instruction in children's diseases, including, of course, the diet of infancy." At the University of Leeds "the formation of a special children's department at the General Infirmary, including a section for the nutritional diseases of infants, has recently been decided on. The honorary officer in charge of the department will give a course of instruction in the hygiene and diseases of infancy and childhood, infant feeding, etc. It is also proposed to link up the infant welfare work in the city of Leeds with that of the new department." The Council's inquiries on this subject of preservation of the health of infants and children are fortunate, therefore, in coinciding with the establishment of facilities for the giving of the desired instruction. Many other passages in the replies from the schools point in the same direction.

As regards preliminary education in general knowledge it was the view of the Committee that "much advantage would be gained were the minimum age at entrance raised to 18." Concerning the earlier sciences it was urged that "the first duty of the teacher is to teach his own subject as a science" and that he should not be called on to include in his syllabus any material which can be better taught at a later stage of the curriculum. The importance of the study of embryology was insisted on in connexion with the teaching of anatomy, but, on the other hand, it was thought that the student should be spared much of the vast accumulation of minute details with which his textbooks are loaded. As to pathology and bacteriology the Committee quote Sir George Newman, who wrote: "The fact is that, broadly speaking, pathology is medicine; it is the study of disease; it is the first great clinical subject of the curriculum." About normal psychology, of fourteen bodies who have given attention to the interrogation in the circular letter, the majority hold that some instruction should be given by the lecturer in mental diseases, but few regard the subject as falling within the domain of physiology.

These are samples of observations and suggestions. Space forbids further illustrations, but, as pointed out in the report, very especial emphasis was given in many

replies to the question of proper co-ordination of studies. Preventive medicine must largely be in the hands of the clinicians, and an extension of the period of clinical study would, of course, mean a lengthening of the curriculum, though "a block introduced into the course by making provision that the examinations in pharmacology and pathology must be completed before the commencement of the recognized fourth year, could it be made effective, would at least ensure two full years for undivided clinical study"; but that proposal "might have to be accompanied by a diminution and simplification of the teaching demands" of the earlier subjects.

At the end of a full and most thoughtful report the Education Committee, as already indicated, felt compelled to make the following recommendation to the Council:

"The Committee begs to submit to the Council the foregoing report on 'The teaching of the preventive aspects of medicine,' which has been prepared by the Chairman after an analysis of the replies received from the teaching bodies. The Committee is of opinion that the questions which have been raised involve the revision of the whole curriculum in medicine, and suggests that the Council should remit to it for further report the consideration of the methods under which the process of revision may best be carried out."

The Committee's suggestion was accepted by the Council, and the outcome was embodied in a further report which was discussed by the Council at its recent session. This report concluded with three recommendations, which were dealt with separately.

Recommendation I.—Preliminary Sciences.

This recommendation included the four following items:

"(a) That before registration in the Students' Register every applicant shall be required to have passed, in addition to the examination in general education, an examination in elementary physics and elementary chemistry conducted or recognized by one of the licensing bodies;

"(b) That a student who has diligently attended an approved course of instruction in elementary biology in a secondary school or other teaching institution recognized by a licensing body may be admitted to a professional examination in elementary biology immediately after his registration as a student of medicine;

"(c) That before registration as a student every candidate shall produce evidence that he has attained the age of 17 years;

"(d) That specialized instruction in physics, chemistry, and biology, in their application to medicine shall be included in the professional curriculum, the teaching arrangements in each case to be determined by the licensing body."

These are mainly self-explanatory. It is desired that, in addition to his examination in general education, the student shall have received instruction and passed an examination in elementary physics and chemistry. By this transference from professional to preliminary study the medical curriculum proper will be correspondingly lengthened, and it is regarded as certain that sufficient instruction in these subjects can be obtained at many of the secondary schools at least in England and Scotland, though in respect of Ireland the position is not so satisfactory. During the discussion in the Council an amendment was moved that biology, instead of being dealt with under (b) in the above recommendation, should be included with (a). This amendment was not carried, and the Education Committee's reason for proposing that there should be a difference was that not nearly so many schools have facilities for instruction in biology as in physics and chemistry. The proposal of the Committee to get over this difficulty as contained in (b) is ingenious—namely, that students who have at secondary schools acquired a sufficient knowledge of elementary biology can proceed to a professional examination in the subject immediately after registration, so that, in effect, all three elementary subjects will in such cases have been cleared out of the way before other studies are entered on. If, however, students have not had the facilities for instruction and examination in one or more of the three preliminary subjects, they can come to the medical schools for tuition, but they cannot be registered until the examinations in physics and chemistry have been passed. This would probably meet the difficulties in Ireland above referred to. Section (c) of the first recommendation—namely, that a student must have reached the age of 17 years, instead of 16 years as at present, was a natural corollary to (a) and (b).

Subsection (d) of the first recommendation—namely, that specialized instruction in physics, chemistry, and

biology, in their application to medicine shall be included in the professional curriculum—indicates one of the lines of reform which were under discussion by the Education Committee, and the Council. These three elementary sciences in their direct application to the later parts of the curriculum, and especially to the clinical subjects, should be taught in connexion with such later subjects, whether as part of the particular course of instruction by the teachers of the clinical subjects, or in a short series of lectures or course of instruction in applied physics, chemistry, etc., the details being left to each individual school.

Recommendation III.—Subcommittees on Curricula.

Passing by Recommendation II for the moment, Recommendation III has now to be referred to. It is as follows:

"That the Council approve the appointment of a number of special subcommittees, as detailed below, 'mixed' in constitution, and each containing representatives of clinical studies, to be charged with the duty of reporting to the Council on the nature of the several curricula, defining essential contents from the standpoint of the adequate training of the general practitioner; of advising as to the proper co-ordination of the work of instruction; and of making recommendations concerning the effective teaching of the preventive aspects of medicine:

1. The preliminary sciences, as related to medicine.
2. Anatomy and physiology.
3. Pathology and pharmacology.
4. Medicine, surgery, and midwifery."

In that connexion, an amendment in regard to Recommendation I was proposed in the discussion at the Council. The amendment was that a decision as to (a), (b), and (d) of Recommendation I should be deferred until the proposed subcommittee on the preliminary sciences had reported. The voting was equal and the amendment was not carried.

Another amendment raised the question whether the preliminary examination in science should be imposed before the present standard of matriculation examinations is raised.

The importance of this point was admitted, and by general agreement an addition was made to Recommendation I as follows:

"That the minimum standard of general education required by the Council for registration as a student should be raised to a standard equivalent to that demanded in other learned professions previously to, or concurrently with, the coming into operation of the requirement of a preliminary examination in science before registration."

Recommendation II.—Professional Examinations.

Recommendation II, which raises a fresh and most important question, may now be referred to. It has long been recognized that in the study of medicine for degree or licence, examinations have had far too much influence on the work of both teacher and student. Under the present system the student's primary object necessarily is to pass his examinations and obtain his legal qualification to practise medicine. He hopes and assumes that in reaching the desired goal he has also acquired a real knowledge of medicine fitting him for practice, but the knowledge is more or less incidental to the work of getting up the subject in such a fashion as will enable him to obtain his diploma. Examinations are indeed a continual nightmare to the ordinary student. Similarly, the teacher, especially if he does not examine his own pupils, feels it his duty to endeavour to secure that his students shall pass their examination in his subject, and is bound to work to that end. The General Medical Council has been so impressed with the undue influence which the examination system exerts on teaching and study that it now proposes to make it possible to give some weight to the student's record of work done in the course of his curriculum. Recommendation II is as follows:

"That in the regulations for the several examinations it shall be provided that the examiners be empowered, in assessing marks, to take into account the duly attested records of the work done by the candidates throughout the course of study in the subject of the examination."

There is no proposal that examinations be done away with, or that the granting of a right to practise should depend on the opinions and reports of the teachers regarding the student's career, but there is at least in this recommendation the element of recognition of the value of

the work done by the candidate during his five or six years of medical study. It seems altogether right that this new factor should be introduced, but it will require to be carefully safeguarded against abuse. When a teacher takes part in the examination of his own pupils, some small element of prejudice for or against an examinee may perhaps inadvertently have crept into the professional mind, owing to demeanour in class or other such cause. Any feeling of this sort may no doubt have some effect under the present system, but there might be more opportunity for its influence if the teacher's record of his student's work were also to count in the decision. On the other hand, where teachers expect to have no direct share in the passing or rejection of their students at professional examinations, there might be some risk of different standards by different teachers in making their records of class work. These are considerations to be borne in mind in working out a scheme, but by no means reasons for rejecting the proposal. In many cases, of course, there is no doubt at the end of the oral and practical examination that the candidate should pass, whilst in many other cases there is no doubt that he should be rejected; but in a doubtful or borderline case a fair and impartial record of a student's work might often turn the scale. One student may be nervous and hesitating under examination, and yet may have done excellent work throughout his curriculum; his record should help to pass him. Another may be glib and skilful in making a parade of knowledge with very little reality behind it; his record should help to reject him. If effect be given in the schools to the new scheme thus proposed by the Council—and it is to be observed that the question whether note of the record should or should not be taken is to be left to the discretion of the examiners—it will be watched with interest and with a hope for good results by all who have the improvement of medical education at heart.

(To be continued.)

THE HEALTH OFFICE OF THE LEAGUE OF NATIONS.

In a leading article, entitled *Health and the League of Nations*, on September 11th, 1920, an outline was given of a scheme for an International Health Bureau under the League of Nations. The scheme was drafted by the International Health Conference convened by Dr. Addison last April, and was adopted subsequently by the Council of the League. The proposal has since been submitted to and approved by the first assembly of the League of Nations held on December 10th at Geneva, and it is now possible to fill in some of the details. It is proposed that the Office International d'Hygiène Publique should remain in Paris to form the basis of an International Health Organization. The office was founded in accordance with the international agreement reached at Rome on December 9th, 1910, to which all the principal countries, with the exception of Germany and Austria-Hungary, subscribed. The new organization will advise the League of Nations on all questions arising out of Articles 23 (f) and 25 of the Covenant of the League. Those in control of the International Office of Public Health are said not only to consent to this arrangement, but also to desire and welcome it. The permanent International Health Organization will consist of (a) the International Office of Public Hygiene, which, completed in a certain way, will become the General Committee, (b) a technical or executive committee, and (c) an International Health Secretariat. The General Committee will be composed of the delegates actually nominated to the International Office of Public Health according to the Rome Convention of 1907, of those subsequently appointed by the countries which were parties to the Convention, and of those nominated by countries not parties to the Convention but members of the League of Nations.

The functions of the health organization will be as stated in our issue of September 11th—namely, (1) to advise the League on matters of health; (2) to establish closer relations between the health services of different countries; (3) to organize more rapid interchange of information when it is necessary to take immediate precautions against disease (such as epidemics) and to

simplify rapid action where such information affects several countries; (4) to initiate or revise international agreements for administrative action in health matters, and especially to examine the questions to be submitted to the permanent and general committees with a view to international conventions; (5) to co-operate mutually with the International Labour Organization for the protection of workers against industrial diseases and injuries; (6) to co-operate with the League of Red Cross Societies and similar bodies, in accordance with Article 25 of the Covenant of the League; (7) to give advice on international questions of health to other voluntary organizations; (8) to organize health commissions when requested.

The General Committee is to meet at least once a year in Paris, and the Council of the League has power to call an extraordinary meeting if necessary. The General Committee may appoint subcommittees to study special questions. Any delegate may employ technical advisers, but such advisers will not have the right to vote.

The Technical Committee will consist of four members from the delegates of the States permanently represented on the Council of the League, five other members chosen by the General Committee with due consideration of scientific value and geographical representation, the President of the General Committee, a representative of the League of Red Cross Societies, and a representative nominated by the International Labour Organization. The Technical Committee will meet at least four times a year, and can be called more often in the event of urgency. It can form subcommittees, and call upon technical advisers in special questions. Its deliberations and those of its subcommittees will be submitted to the General Committee and to the Secretary-General of the League of Nations through the Medical Secretary. The President and members of the Technical Committee will be chosen for three years, but will be eligible for re-election.

The Secretariat will consist of a Technical Secretary and staff. The Technical Secretary will be nominated by the Committee in agreement with the Secretary-General of the League. He will have the right to communicate directly with the Secretary-General and with the health services of all the Governments, and to attend all meetings of the Technical Committee, of the General Committee, and of all subcommittees. The staff will consist of persons of different nationalities, nominated by the Technical Committee in consultation with the technical secretary. The location of the International Secretariat of Health will apparently be the same as that of the League of Nations.

The object of all this machinery appears to be to elaborate new international agreements and to revise agreements already existing. Such new projects or revisions will be submitted by the Technical Committee for examination and approval by the General Committee; for the adoption of the agreement a two-thirds majority of the General Committee will be necessary. When any proposed agreement affects international commerce or communication the Committee must confer with the Economic Organization and with the Organization of Communication and Transport. If the General Committee approves the projected agreement it will be signed by the President and by the Technical Secretary, and handed to the Secretary-General of the League. The Council of the League will then submit the proposed agreement to the Governments interested, which will be invited to instruct their plenipotentiaries to sign the agreement without delay. Each country will be asked to ratify such agreement before the expiration of one year, or before the expiration of that period to notify the Secretary-General of the reason why it has not done so. Each agreement ratified will be registered by the Secretary-General, but it will be binding only on the countries which have ratified it. The members of the General Committee undertake to present annual or special reports on the measures taken in each country to carry out the clauses of the agreement. Non-signatory countries will be invited to furnish reports on matters bearing on the objects of the agreement.

It is evident that the proposed International Health Organization is grandiose in nature, and under certain conditions may have far-reaching results. But it often happens that councils, such as that of the League of Nations, having set up a vast machinery of committees and subcommittees, break up with a feeling that they have accomplished a great work; whereas they have not dealt with the vital factor in the situation. If the International

Health Organization is to be anything more than a method for dealing with unemployment amongst officials, the really important matter is the appointment of the superman who is to be the Technical Secretary. On him will depend the success or failure of the whole organization. In the first place, the secretary must be a medical man of wide outlook and extensive knowledge, not necessarily an expert in any one branch of medicine. Secondly, he must have administrative capacity. Thirdly, he should speak two or three languages in addition to his own. Fourthly, he should have the power of choosing suitable people to fill gaps in his own knowledge or capacity. Lastly, he must possess infinite tact in dealing with governments and with various organizations, many of which will be jealous of their prestige and position. With energy and enthusiasm such a man might make much of the International Health Organization, notwithstanding all its complicated machinery of offices, councils, committees, and subcommittees. Without such a man it will be but a meagre feast to which the General Committee at its annual meeting and the Technical Committee at its quarterly meetings will sit down. It will be interesting to see which nation will produce this prodigy. He may become Registrar-General for the World, surveying mankind from China to Peru.

CUMBERLAND TUBERCULOSIS COLONY.

As the Cumberland Council was the first in the field in establishing an experimental farm, it is now one of the first councils in England—if not the first—to establish a colony for the industrial treatment of tuberculosis as a charge on the public funds. Dr. Morison, the medical officer of health for the county, first suggested the scheme in 1914, but the outbreak of the war prevented any steps being taken. In September, 1919, however, the Council purchased the Englethwaite Hall Estate at a cost of £5,000. The estate consists of a mansion house, a small residence, a cottage, outbuildings, a range of glass-houses, and about 32 acres of land. Its situation is in many respects ideal. It stands on rising ground, with an easy gradient, on gravel soil, and has a southern aspect. It is in a sparsely populated district, the nearest village being three-quarters of a mile distant, and it is within three minutes' walk of a station on the Midland Railway, and about six miles from Carlisle.

The necessity for such an institution is apparent. Consumption is still a vital problem, and it is estimated that since 1914 there has been an increase of 12 per cent. in the death roll from tuberculosis in the country. In Cumberland 2,675 cases in all have been notified since 1912, while the number of deaths in the county during the last six years has totalled 1,461. There is in the county a sanatorium with sixty-four beds for cases of tuberculosis, but, as stated in a leading article in the *JOURNAL* for December 4th, 1920, the results of open-air or sanatorium treatment "have admittedly been disappointing, and this experience has not been peculiar to this country; nowhere have the first hopes been realized." The enthusiasm with which the colony treatment of tuberculosis has been taken up points strongly to the fact that the sanatorium treatment is not a final solution of the problem, and this new experiment will be watched with interest. The first colony of the kind was started near Edinburgh in 1910, and at the present time several English county councils have schemes in progress for the establishment of tuberculosis colonies; while, of course, the Papworth colony, as is well known, is interested in the subject.

Although there has been no formal opening there are already twenty-five inmates in residence at Englethwaite, and, with the approval of the council, plans have been submitted to the Ministry of Health which will increase the accommodation to 100 patients. In the first instance it is intended that preference shall be given to ex-servicemen. During the period of reconstruction and adaptation of the premises to the present purpose Dr. Kenneth Fraser has taken charge, and he has devoted himself wholeheartedly to the work. He has had the advantage of the advice and help of Dr. Morison, an official with progressive views and expert knowledge, and has been well backed up by an enlightened and sympathetic Hospital Committee. On the invitation of this committee representatives of the press in the county have recently visited

the colony and the public have been made acquainted with full details of what has already been accomplished.

Dr. Mark Fraser, a brother of Dr. Kenneth Fraser, has been appointed resident medical superintendent, and has taken up his residence in the smaller detached house in the grounds, and already a beginning has been made with several industrial occupations. A market garden of about eight acres has been started, while poultry keeping with the intention of going in for egg production on an extensive scale has been commenced. Some hundreds of day-old chicks have been bought from strains of high-laying records. For the present year only the rearing of some hundreds of Game Cross Orpingtons and other varieties for sale for table use is being developed, in order that some capital outlay may be written off within twelve months, and it is also intended to fatten geese and ducklings for the market. A start has been made with a joinery department, and a cabinet-making department will be run in combination. Some six shelters of an excellent model have been purchased from the Papworth colony, and one or two huts, one semi-intensive poultry house, and one breeding pen have been bought. These have been erected by the patients, and it is intended that all future constructional work will be done by the colonists themselves. Some military huts have been purchased and converted into workshops. Here boot and shoe repairing departments have been organized, and clog making has been started. Pig keeping is another industry which is contemplated.

The workshops are being run on strictly commercial lines, and the whole of the profits, after allowing a bonus for the men, will go to a fund for the benefit of the patients themselves, in the way of providing clothing and all the things which come under the heading of "after-care." There will be plenty of work for every inmate. Each case is being carefully studied as to his future occupational outlook. The minor can forsake his trade and become a market gardener; the barber can become a carpenter. It has not been found that men have any hesitation in so drastically reconstructing their lives or that the results are disappointing. Certain trades will be taught in combination. Each patient in training for market gardening, poultry keeping, and pig keeping will receive at least three months' training in each, so that on his discharge he may be fit to take up a small holding.

Even after discharge the medical superintendent will keep the men under supervision, and if any show signs of a return of the disease arrangements will be made to take them back to the colony. It is hoped, of course, after discharge that the men will be able to earn their own living at the trades which they have been taught, but it is considered that no colony scheme will be complete which does not provide housing accommodation for the colonists who, after the completion of their training, desire to remain on the colony. This means village settlements for tuberculous patients.

These village settlements will amount to the segregation of tuberculous patients from the general community, and should be an important factor in the stamping out of tuberculosis. Although for the time being these have been turned down on grounds of national finance, the question is bound to be reconsidered at an early date, because on the successful solution of the problems of "after-care" of which these settlements must form an important part, the whole future of the colony idea depends. Meanwhile at Englethwaite the outlook is promising. The equipment has been carefully selected, and is of the best quality, and the general arrangements have met with the cordial approval of the representatives of the press of the county.

ASSOCIATION OF CERTIFYING FACTORY SURGEONS.

THE annual meeting and dinner of the Association of Certifying Factory Surgeons were held at the Queen's Hotel, Manchester, on December 15th, 1920, under the presidency of Sir Thomas Fairclough. The regular business of the meeting included the election of officers for the coming year, Sir Thomas Filitcroft, Dr. W. F. Dearden, and Dr. T. Watts being re-elected to the offices of president, honorary secretary, and honorary treasurer respectively. The auditors' report showed the financial position of the association to be highly satisfactory.

The report of the council, in dealing with the decline in membership during the war, urged upon members the necessity for assisting the efforts of the secretaries by

personal canvass of non-members or by at least sending in their names. Particular interest was taken in the section of the report dealing with correspondence between the association and the chief inspector respecting increase of fees. - Considerable dissatisfaction was expressed at the ineffectiveness of the two orders issued by the Secretary of State concerning fees for certifying and for examinations under special rules and regulations respectively. The report pointed out the ambiguity of the two scales now in vogue. It showed that they might be interpreted, as had been the case with some certifying surgeons, to mean that the surgeon is entitled to the half-crown for the visit independently of the shilling for each examination, which, if officially accepted, would undoubtedly have brought about increased remuneration for all examinations. Unfortunately, the departmental interpretation had proved to be that the half-crown still occupied its time-worn position as a covering fee, the only difference being that it now covers the visit and two examinations instead of the visit and five examinations. Compiled as the result of an inquiry, figures were presented which showed that the scale for certifying could not produce any advance in payment for 53½ per cent. of the visits now made, owing to the small numbers presented on each occasion, this again indicating positively the futility of raising the basic examination fee without altering the covering fee for the visit. The chief inspector had stated, in a letter dated June 28th, that the Orders had increased the fees 100 per cent., but obviously this could only happen in the rare instances when five or more are to be dealt with at one visit.

It was unanimously agreed that the council should communicate further with the chief inspector, pointing out the views of the association and the firm conviction of the meeting regarding the necessity for rendering the 100 per cent. advance effective for all visits by making the covering fee 5s. instead of 2s. 6d. It was further agreed that the attention of the chief inspector should be directed to the circumstance that the Government is still paying the ancient fee of 3s. for two visits, two inquiries, and one report on each case of industrial disease or poisoning, with a suggestion that the minimum should now be not less than 7s. 6d.; also that all mileage rates should be the same—namely, 1s. for each mile or a portion beyond the initial mile.

ROYAL MEDICAL BENEVOLENT FUND.

At the last meeting of the Committee, held on December 14th, 1920, thirty cases were considered and £315 voted to twenty-five applicants. The following is a summary of some of the cases relieved:

Daughter, aged 61, of M.R.C.S. Eng. who died in 1835. She and her mother, who died in 1906, were left with very limited means. The applicant now has only £1 per week, and, owing to ill health and increased cost of living, finds it impossible to pay her way, and has got into debt. Voted £12 in twelve instalments and a special grant of £9 towards debts.

Widow, aged 71, of M.D. Glasg. who died in 1833. Lives with a sister who has £10 and applicant has £50. They endeavour to supplement this by letting rooms, and last year received from this source £25. Rent £34. Voted £12 in twelve instalments.

Widow, aged 75, of M.R.C.S. Eng. who died in 1883. Applicant was left totally unprovided for with four children, all of whom are now married but are unable to assist her. Her only income is the old age pension (£0s. a week) and occasional gifts from friends. Pays £3. per week for one room. Relatives who in the past helped are now all dead. Voted £18 in twelve instalments.

Widow, aged 31, of M.B. Edin. who had for two years worked on a pensions board and previously worked as a locomotive and died in 1920. Applicant left quite unprovided for with two children, aged 11 and 13. The board collected a sum but she was exhausted. Having no relatives to be a post. Would like to get the children into a home. Expenses: Rent £1 a week, board 25s. a week, storage of furniture 5s. Voted £12 in twelve instalments.

Subscriptions may be sent to the Honorary Treasurer, Sir Charters J. Symonds, C.B., F.R.C.S., at 11, Chandos Street, Cavendish Square, London, W.1.

The Royal Medical Benevolent Fund Guild is overwhelmed, in these days of exorbitant prices for clothing and household necessities, with applications for coats and skirts for ladies and girls holding secretarial posts, and suits for working boys. The Guild appeals for second-hand clothes and household articles for the benefit of the widows and children who in happier times would not have needed assistance. The gifts should be sent to the Secretary of the Guild, 43, Bolsover Street, W.1.

British Medical Journal.

SATURDAY, JANUARY 8TH, 1921.

WHITLEY COUNCILS.

AMONGST the experiments in organization which we owe to the reconstruction period, few are of greater interest than the Joint Standing Industrial Councils, for which, as chairman of the Reconstruction Committee, the Deputy Speaker, Mr. J. H. Whitley, stood sponsor in 1917. Although the point of contact between the medical profession and the Whitley system may not be obvious at the first glance, it is not in reality far to seek. Apart from the fact that the substantial success of the experiment would profoundly modify the whole organization of industry, and would thus affect the conditions of life of every class in the community, the system is not applicable to industrial workers only; it has, in fact, been applied to the case of elementary and secondary teachers in the service of local education authorities. This being so, we cannot afford to overlook the possibility that the new machinery may be applicable, with or without modification, to the special problems of certain groups of medical practitioners. New circumstances often call for new expedients, and every fresh phase of organization merits careful scrutiny as a preliminary to either acceptance or rejection.

If neither of these arguments is calculated to break through the indifference of the average man to the method by which the tangible benefits he looks for from professional organization are obtained, there remains one of potent appeal. The graduated Civil Service bonus, with its sliding scale, has doubtless, during a period of rising prices, been his ideal standard for post-war remuneration. That bonus was the fruit of the deliberations of a subcommittee of the Civil Service National Joint Council, and the method of its achievement is worthy of consideration. Finally, whether for good or for ill, at least two National Whitley Councils at present exercise a determining influence on some of the conditions of employment of several thousand medical practitioners. That, however, is a position which demands more detailed study than the limits of this sketch will permit, but in face of these facts no apology need be made for focussing medical attention upon the principles and practice of Whitleyism at the present time.

The idea underlying the Whitley experiment is that there exists a substantial community of interest between the employers and the workers in any given industry or service. On this basis the procedure hitherto applied to the settlement of disputes by conciliation boards composed of representatives of the parties concerned may be utilized for their prevention. To accomplish this goodwill on each side is needed, and a continuous joint review by the parties concerned of the conditions from which disputes commonly arise. The sphere of the joint council thus conceived embraces the whole field of conditions of employment and remuneration. It is positive as well as negative, for the point at which prevention of

disputes passes into the promotion of better conditions is hardly determinable.

The machinery proposed is a committee consisting of an equal number of representatives of the employers and the employed in each industry or service, exercising continuous supervision over conditions of employment, and acting as the accredited organ for communicating the wishes of the industry to the government and the public. A complete Whitley system for an industry involves the coexistence in each case of at least two and probably three types of joint council—the national, the district, and the works. In order to ensure adequate consideration of the needs of special grades and groups, the councils can work through special or grade committees, the members of which need not necessarily be members of the councils concerned. Although an impression to the contrary exists in some quarters, the adoption of the system is purely voluntary. Moreover, since only those reports may be issued to which a majority on both sides of the Council have agreed there is no fear of compulsion within the Council itself. In the absence of special business, the National Council is bound to meet at stated intervals to review the general situation.

Turning from the general principles to the practice of Whitleyism, we find in existence between sixty and seventy National Councils, and more than two hundred district and departmental councils. A few of these are in suspense, owing to the failure to secure a basis of agreement, or to the refusal of the parties concerned to put the agreement reached into effect. The majority of these Councils are of the orthodox industrial type, but, as already indicated, three cover various professional and administrative workers, and of these two—the Civil Service Administrative Clerical and Legal Departments Joint Council, and the Municipal, Clerical, Technical, and Administrative Services Joint Council—cover an appreciable number of medical practitioners. The third is the modified Whitley Council for Teachers, known as the Burnham Committee.

The record of these three councils includes the substitution of order for chaos in the grading and remuneration of the teaching staffs of local education authorities, the report under which the reconstruction of the Civil Service is now in progress, the report on the cost of living already mentioned, and the adoption of a scale of salaries and a grading scheme for the clerical and administrative workers in the municipal services. Here, it is true, some difficulty has arisen in the execution of the scheme. It is, however, too early to say whether the difficulties of the case will prove insuperable. This record is in itself sufficiently striking to call for a more detailed consideration of the method by which it has been produced. Meanwhile no verdict can be passed upon a system which is obviously in its infancy. All that has been attempted here is to record in outline the successive stages of its development, so that the reader who has not hitherto given attention to the system may be able to appreciate the conditions determining failure or success.

WHAT WE CANNOT AFFORD.

THOSE who recollect the exhortations to the Minister of Health to mobilize research armies for the "conquest" of zymotic diseases, which emanated little more than a year ago from precisely the organs which in the last weeks have held the extravagance of the Ministry up to public execration, will probably see in

the incident only another example of the frivolity or tendentiousness which are thought to characterize popular journalism. We believe, however, that the true explanation is less simple, and that it will be instructive to show that the optimism of 1919 and the pessimism of 1920 are the necessary consequences of an ignorance which it is the duty of our profession to try to dispel.

The fundamental distinction between the master of any intellectual discipline and the tyro is that the former sees his subject as a continuous whole, while to the latter it is a mass of disconnected ingenuities. Anyone may convince himself of this truth by, for instance, comparing the way in which a trained mathematician solves elementary problems with the procedure of an equally able but untrained worker; in the one case there is a certain uniformity about the methods of attack—the several solutions have a family resemblance; in the other each problem is special—a law to itself.

The application of this train of thought to medical science is direct. In the beginning man was a strict realist; there was "health" and there was "disease," or rather "diseases"; disease was something which attacked man, and the problem was to drive this something out or to keep it away. Thus the first doctor was the witch doctor. An attempt to break down primitive realism and exorcise the exorciser, the witch doctor, was made by Hippocrates, who taught that disease was not a thing but a process, and his system, as Sydenham wrote, "exhibited justly such operations of Nature as she puts forth in the diseases of humanity. The vain efforts of a wild fancy, the dreams of the sick man, it did not exhibit." The degenerate Greek science of the Empire reincarnated the witch doctor; for this Galen's realism and its pre-renaissance exponents are responsible. Medical research since Harvey has progressed in such a way that no intelligent medical student now runs much risk of becoming a realist. But some of the methods which have freed him from the ancient snare and, perhaps, the language in which he sometimes describes them, have deceived the public. Thus we, as a profession, connect by an unbroken chain of causality—let us suppose—diseases of the enteric group and contamination of the food supply. We are, indeed, satisfied that substantial protection against a particular micro-organism is afforded by antityphoid vaccine, against other organisms epidemiologically similar by paratyphoid vaccines. We do not, however, suppose that were the entire community so protected, but no measures taken to secure the food supplies, water-borne and food-borne diseases would cease to scourge mankind. We should, on the other hand, confidently anticipate the emergence of other epidemiological forms against each of which we should hope a specific protection might be discovered; but we should hold that as each form was conquered another would take its place in endless series, so long as the original source of and predisponent to disease existed.

Here precisely is the difference between the physician and the layman, or medical correspondent of the daily press. The layman is a realist. He honestly believes that if the "cause" of "influenza" could be shown on a plate and a suitable vaccine prepared, we should then be in a position to make an end of "influenza." This being admitted, there is no inconsistency between the demand for intensive "team work" at public expense and the furious outcry against, say, expenditure on dentistry or health centres. The layman, like the late German Emperor, dreams of a short brilliant campaign which shall

"conquer" the zymotic diseases by discovering their "germs" and providing vaccines. The world is to go on just as before, save that these realities are to be eliminated. The physician remembers *naturam expellas furca tamen usque recurret*, and is less optimistic.

It has often been said that a community can purchase health, but the question must be faced whether the price to be paid is not so high that an attempt to find it will dissolve the community. It is not the business of medical men as such to answer that question, but it is their duty to state that the price must be very high, that the task of preventive medicine is something larger than the campaigning against germs.

The rationale of a hygienic life has been known for thousands of years. Celsus—with his prescription of a varied regimen, of moderate exercise, sometimes "to be in the city, sometimes in the country, the open air above all"—was at one with Dr. Leonard Hill; but his rules were qualified by a little phrase which in his time made them of small effect to a majority. They only applied to the man who could live as he pleased (*suae spontis est*). The task of the sanitarian has been to determine which of the factors governing the lives of those who cannot live as they please are most noxious. Eighty years ago the housing question was first seriously raised and urban sanitation taken in hand. The most pessimistic will not deny that the second problem is now less formidable; the most optimistic cannot regard the housing position with equanimity. In the meantime other difficulties have either been created or increased by industrial progress, such as the consequences of mass production in factories upon the health of the operatives. We now seek to know how the millions who must live their lives under conditions unlike those of primitive man, unlike those of the small minority to whom most ancient literature was addressed, can be safeguarded physiologically. In comparison with this problem that of "unemployment," a mere affair of distribution, is simple; yet the question of "unemployment" is still acute. Sir George Newman in his first report to the Minister of Health wrote: "Our business at the Ministry of Health is not to build for to-day or to-morrow, but for the future, not to attempt to settle forthwith this or that or the other local specific health problem, but to view such problems as parts of a whole, and slowly but surely to lay foundations which will endure."

This is the sentiment general among medical men, and is utterly repugnant to the intensive campaigning spirit of the lay journalist. We are not only to recognize for ourselves but to teach our fellow citizens the principle of continuity between physiology and pathology, so that they may learn that, for instance, dental prophylaxis is not an extravagant luxury, nor the teaching of hygiene in schools an attempt to deprive the poor man of his beer.

But above all we, as members of the medical profession, must preach the sermon that the way to national health is long and toilsome, and that the "path to a clear-purposed goal" does truly lead "a long, steep journey, through sunk gorges, o'er mountains in snow."

Those who tread this path, whether "bureaucrats" or private practitioners, need expect little encouragement from the popular press; they are more likely to encounter opposition and ridicule. But if, as we believe, this opposition is not the fruit of ill-will but of ignorance, the future is not wholly dark provided the medical man lives up to the original meaning of his popular appellation.

NEW YEAR HONOURS LIST.

THE New Year Honours List as it affects medicine is unusually short, and is chiefly remarkable for the recognition accorded to medical journalism, as an element in the life of the nation, by the knightships conferred on the Editors of the *Lancet* and of the *British Medical Journal*. Dr. William Hodgson, who also receives the honour of knightship, has done much public work in the town of Crewe; he was a member of the town council for many years, and mayor in 1892-3. He has been a member of the Cheshire County Council since its formation; he is an alderman and vice-chairman of that body, and chairman of the Cheshire Education Committee. He is also a member of many other county committees, and has set an example to other members of the profession which should encourage them to take their share in the public life of the localities in which they practise. He is a member of the Insurance Acts Committee. Sir E. Cooy Bigger is medical member of the Local Government Board in Ireland, chairman of the Irish Public Health Council and Central Midwives Board, and Crown representative on the General Medical Council. Sir Charles Ryall is a member of the Council of the Royal College of Surgeons of England, and Sir Frederick Hewett is a medical member of the household of the King and of Queen Alexandra. The knightship to Sir P. J. Michelli recognizes important services rendered to medicine in the department of tropical diseases. He has been secretary of the Seamen's Hospital since 1887 and of the London School of Tropical Medicine since its foundation in 1899. He has recently had a large share in carrying through the establishment of the School with its special hospital in the buildings at Endsleigh Gardens. A full list of the medical honours is printed at p. 61.

MEDICAL DRAINAGE OF THE BILIARY TRACT.

By a happy combination of ideas derived from S. J. Meltzer's physiological observations on the one hand, with the use of Einhorn's duodenal tube on the other hand, Dr. B. B. Vincent Lyon of Philadelphia has during the last three years worked out a method of draining the bile ducts and gall bladder which has already given excellent results in the diagnosis, prevention, and treatment of biliary disease, and gives promise of far-reaching importance. In 1917 Meltzer formulated his conception of contrary innervation as applied to the filling and emptying of the gall bladder; Oddi's sphincter at the lower end of the common bile duct and the musculature of the gall bladder are supplied with inhibitory and motor fibres from the splanchnic and vagus nerves, which act antagonistically to each other, so that when the sphincter is relaxed the gall bladder contracts and vice versa. He also showed that the application of a solution of magnesium sulphate to the mucous membrane of the duodenum was followed by relaxation of Oddi's sphincter, a result which was not produced when the salt was taken by the mouth. His hint that this observation should be utilized in human disease has been acted on by Lyon,¹ who has published a series of papers containing observations and suggestions of great importance for future developments in medical and, indeed, in surgical practice. Lyon believes that the application of magnesium sulphate to the duodenal mucosa induces contraction of the gall bladder, and that incision of the gall bladder or disease of its walls removes the normal antagonistic action of the gall bladder and Oddi's sphincter, so that bile then runs continuously into the duodenum. The technique of the introduction of the duodenal tube is too long to quote; but it may be mentioned that the patient is examined twelve hours after a meal, contamination of the duodenal contents from the mouth and stomach being obviated by frequent washings; when the tube has entered the duodenum 75 c.cm. of a 33 per cent. solution of mag-

nesium sulphate is introduced, and the contents are then gently aspirated. In health the first bile thus obtained is of a light yellow-golden colour, and comes from the common bile duct; after a short time the bile suddenly changes to a darker golden yellow, becomes more viscid and larger in quantity; this bile is regarded as coming from the gall bladder; later bile of a lemon colour, thinner and more limpid than the other two, follows and is believed to be that freshly secreted by the liver. The normal gall bladder contains $1\frac{1}{2}$ oz. to $2\frac{1}{2}$ oz. of bile, but in stasis or atony of the gall bladder as much as six ounces may be obtained provided, of course, that the cystic duct is patent. These characters of the bile change as the result of biliary infections, and comparison of the three samples, which can be separated into different bottles, will indicate what part the gall bladder or common bile duct—is infected or mainly involved. Chemical, microscopical, and bacteriological examination of the bile can thus provide an early diagnosis; and, as Dr. G. E. Brown² points out in a recent article on "The Meltzer-Lyon method in the diagnosis of infections of the biliary tract," early cholecystitis can be detected at a stage when the clinical manifestations—indigestion and minor colic—are vague, and the gall bladder does not show any thickening or colour changes to the naked eye, so that bacteriological examination of the aspirated bile provides the surgeon with data he might fail to obtain from an exploratory laparotomy. When more than two and a half ounces of gall-bladder bile is obtained by aspiration, the diagnosis of stasis is justified, and by means of repeated aspirations this condition, which is of such importance in favouring infection and cholelithiasis, can be obviated. In cholelithiasis the bile may convey a gritty feeling to the finger, and microscopically show clustered masses of precipitated bile salts or pigment; on one occasion small concretions were aspirated through the tube, and several times calculi too large to be recovered by the tube were passed by the bowel after aspiration. Treatment of simple catarrhal jaundice by repeated aspiration of bile and subsequent disinfection with permanganate or silver nitrate solution diminished the duration of the disease by half, and probably minimized the risk of sequelae. This method is not only of use in the treatment of early inflammations of the gall bladder and bile ducts, but may be valuable in infections persisting or recurring after operation. Further, there is a wide scope for investigation on the lines opened up by this method, on the action of cholagogues, on the early stages of biliary stasis, on the so-called functional disorders of the liver, and on the changes of the pancreatic juice.

A SIXTEENTH-CENTURY SCHEME FOR A LONDON UNIVERSITY.

ALTHOUGH Sir Humphrey Gilbert (1539-1583), the half-brother of Sir Walter Raleigh, is best remembered as a navigator, the *Dictionary of National Biography* points out that the scheme that he laid before Queen Elizabeth, about the year 1572, for "the erection of an Aclademy in London for education of her Maiesties wards, and others the youth of nobility and gentlemen" adds more to his literary fame than anything he ever undertook either as a soldier or a colonist. This curious anticipation of modern efforts to obtain a teaching as well as an examining University in London has attracted the attention of Mr. L. M. Griffiths, who reproduces parts of Gilbert's MS. (British Museum, Lansdowne MS. 98) in a short but scholarly note.³ Although educated at Eton and Oxford, Gilbert spoke disparagingly of Oxford and Cambridge, considering that the students "are drawn into licentiousness and idleness; and, therefore, yt were every way better that they were in any other place than theare." His plan was intended to find a remedy for their deficiencies, and it is interesting to glance at the provisions for medical education: "There shall be

entertained one Doctor of phisick, who shall one day reade phisick and another daie Chirurgerie, in the Englishe toung, touching all Kinds of Vlcers, Sores, Phistiloes, Woundes, Etc. Together with all kindes of medicines for the same, as well Chimice (chemical) as otherwise." . . . "The Phisition shall practize to reade Chirurgerie, because thorough wante of learning therein, we haue verie few good Chirurgesons, yf any at all, by reason that Chirurgerie is not now to be learned in any other place than in a Barbers shoppé." Research was specially indicated in the following words, which somewhat resemble those of Harvey's exhortation of 1656, that "this phisition shall continually practize together with the naturall philosopher, by the fire and otherwise, to search and try out the secretes of nature as many waies as they possible can." The keeper of the library has his duties defined, and the Copyright Act is anticipated in the proviso that "all Printers in England shall for ever be charged to deliuer into the Library of the Achademy, at their owne charges, one copy, well bownde, of euery booke, proclamacion, or pamphlete that they shall printe."

THE INSURANCE RECORD CARDS.

THE new medical record cards for insured persons came into use on January 1st; they are intended to contain a complete record of all the illnesses for which the individual is treated during his or her life. The system, which has been devised as an improvement upon that in use before the war, has been severely criticized by those newspapers which appear to be engaged in a campaign against the Ministry of Health. Granted the condition—namely, a medical service as part of a compulsory insurance scheme to which the State contributes—we do not think the charge is well founded. Under any State system there cannot be the absolute secrecy which exists in private practice, but the Interdepartmental Committee, over which Sir Humphry Rolleston presided, recommended precautions which, if observed, ought to prevent leakage. The card, with its medical notes, remains in the custody of the doctor until the insured person leaves the neighbourhood or for some other reason changes his doctor; in that case it is the doctor's duty to close the "window" envelope, as described in the SUPPLEMENT this week, and send it in another closed envelope by post to the clerk of the Insurance Committee of the district. We do not find that it is anywhere specifically stated that the doctor should close the "window" envelope before parting with it, but no doubt this is the intention. In the event of an insured person's death his doctor will forward his record card to the Insurance Committee; by it the card will be transmitted to the Insurance Department of the Ministry of Health; there it will be dealt with at once unopened in a clearing house; subsequently it may be opened and used for statistical purposes under the direction of the medical staff of the Insurance Department. The system has been fully explained in a memorandum addressed by the Ministry to doctors engaged in insurance practice; but others may find the article published in the SUPPLEMENT useful in recalling the circumstances. It is also objected that there is a breach of professional confidence because the Ministry, through its medical officers or persons they may appoint, has the right to inspect the records in the hands of the doctor. Here again we have a consequence of the interference of the State in matters so intimate as personal health; the risk was pointed out during the discussion of the first Insurance Bill, but Parliament, with, so far as can be judged, the full approval of the persons who were to become insured persons, decided that the benefits of the insurance scheme would more than compensate for any disadvantages that attend State interference. The risk that some confidential clerk employed by the medical officers of the Ministry should come across the record of a private acquaintance exists, but it is small and ought to be sufficiently safeguarded

by the obligation of discretion and secrecy which the Ministry will no doubt impose on persons so employed. The frequency with which inspections of records are made does not, of course, affect the principle, but it may be doubted whether it would often be profitable to resort to this method. The data to be so obtained would not, as a rule, be of a nature to yield more than the simplest statistical results. The experience of the census is sufficient to prove this, and to prove also that a large statistical staff under expert direction would be necessary to achieve even so much. In saying this we are aware that the Insurance Acts Committee desired that the prime purpose of the records should be clinical and not statistical or administrative, but it is difficult to conceive any application of the data which would not involve the statistical method. The Conference of Local Medical and Panel Committees has agreed that the new form of record shall be given a trial, and no doubt much will be learnt both as to the merits and defects of the method during this year.

ALKALOIDS AND GLUCOSIDES.

M. EM. BOURQUELOT, professor of pharmacy in the School of Pharmacy of the University of Paris, has recently communicated to the Académie de Médecine a paper¹ describing a number of glucosides which he has recently prepared. Incidentally he deals with the history of the discovery of alkaloids and glucosides. The first alkaloid to be isolated was morphine, and its discovery is generally attributed to a Hanoverian pharmacist, Sertürner, whose report on its isolation was published in 1806. He showed for the first time that it behaved like an alkali, forming salts with acids, but Bourquelot points out that the same body had been identified some years earlier by Dérogne, a Paris pharmacist. Dérogne published his results in the *Annales de Chimie* of the 30th ventose of the year XI (March 20th, 1803). By precipitating a solution of opium with potassium carbonate he obtained a crystalline body which he called a salt, although he recognized that it was not really of that nature. Dérogne's method of obtaining what he called the "essential salt" of opium was in principle the same as is used for producing the alkaloids, which are now known to the number, it is said, of 250. Pelletier isolated emetine from the ipecacuanha root in 1817, strychnine was obtained in 1818, and brucine in 1819, quinine and cinchonine in the following year, and codeine in 1831. The search, however, soon showed that alkaloids were not the only active principles that occur in plants. In 1820 a French pharmacist—Leroux—obtained salicin from willow bark; he supposed it to be an alkaloid, but Gay-Lussac showed that this was an error, as the body was neutral and did not form salts with acids. Certain other bodies of a similar nature were identified, and as, when decomposed, they were found to yield glucose they were called glucosides. Certain glucosides are hydrolyzed by emulsin, and M. Bourquelot has made use of the method founded on this observation. When he began the inquiry in 1901 only ten glucosides were known. He has added many, eleven of them from plants which are used, or have been used, as domestic remedies. Such a familiar shrub as the elder (*Sambucus nigra*) yields the glucoside sambunigrin, the cherry laurel (*Prunus lauro-cerasus*) prulaurasin, the leaves of the yew (*Taxus baccata*) taxicatin, and so on for veroin, hepatica, scabious, and several others. He has found glucosides also in a number of plants not used in medicine. Altogether 208 species of plants were examined, and evidence of a glucoside found in 149, although in only 56 was it isolated.

CERVICAL DEFECTS.

A RECENT number of the Italian journal which is devoted to the surgery of the locomotive organs² was entirely given up to an article of 104 pages on congenital

¹ *Bull. de l'Acad. de Méd.*, November 30th, 1920.

² *La Chirurgia degli Organi di Movimento*. Direttore, Dott. V. Putti. Vol. iv. Fasc. 4, with 81 figures in the text. Bologna: L. Capelli. October, 1920.

pointed out by the Committee, abolition of the open coal grate will diminish expenditure in that brick fireplaces, large flues, and chimney stacks will not be required; this should be found to counterbalance the cost of the smoke-preventive equipment, and in some instances it is anticipated that adoption of modern heating equipment will lead to an actual saving. The Housing Commissioner is prepared to confer with local authorities on the question of a central installation for the hot-water supply and heating of a number of houses. Against the extra cost of such a system should be set a considerably lessened cost of construction.

THE famous *tisanes* which constitute the basis of domestic therapeutics in France are virtually unknown on this side of the Channel, and only a few old-fashioned housewives are familiar with the demulcent properties of marsh mallow, the sedative effects of verberna, the expectorant qualities of eucalyptus leaves, the diuretic properties of couch-grass (especially when associated with nitre), and the alleged depurative action of sarsaparilla. By far the greater part of the medicinal herbs utilized in this country are imported, in spite of the fact that many of them might very well be cultivated at home. It is even more surprising to learn that in France, where *tisanes* are so popular, huge quantities of herbs are imported, to the detriment of the national exchequer. It may not be without interest to look down the list of these importations. Arnica figures for four tons and costs £20 a hundredweight for the flowers, £7 for the root; buckthorn (*Rhamnus frangula*), a favourite laxative for children, 21 tons at £6 the cwt.; mullein, a popular demulcent, 4 tons at £24 the cwt. Camomile flowers, stomachic and antispasmodic, are in great request, since, in addition to being largely cultivated in France, 41 tons are imported at £24 a cwt. Far and away above the other herbs in point of popularity is couch-grass, of which as much as 127 tons enters France every year at £7 a cwt. Eleven tons of male fern were imported at £26 a cwt., and nearly the same weight of ash-tree leaves for purgative purposes. Seventeen tons of gentian and 70 tons of marsh mallow seem reasonable, but it is difficult to imagine that it should be necessary to import nearly 5 tons of the ordinary common nettle and 94 tons of cherry stalks, the latter being reputed highly diuretic. Fifty-eight tons of coltsfoot (*Tussilago*), another demulcent, and 42 tons of violet petals, the last named at £36 a cwt. We have not exhausted the list by any means, but we have said enough to establish the importance of this branch of commerce, especially when it is borne in mind that no mention is made of such drugs as digitalis and hyoscyamus and the like.

THE Departmental Committee on Smoke and Noxious Vapours Abatement, which was appointed in 1914, and resumed its work in the early part of 1920, formed the conclusion that, even in industrial areas, at least 50 per cent. of the pollution of the atmosphere by smoke—with the attendant evil effect on human health, as well as on vegetation and agriculture, on live stock and milk—is due to domestic chimneys. In view of the many State-aided housing schemes lately begun or projected the Committee issued on June 1st an interim report on the methods that might be employed to minimize the production of smoke in new houses, where "a unique opportunity for constructive reform" exists. An account was given in our issue of August 7th, 1920 (p. 220), of the investigations and conclusions set out in this report. The Ministry of Health, which had previously drawn the attention of housing commissioners to the report, has now issued a general housing memorandum (No. 40), in which are indicated in general outline the best methods for putting the Departmental Committee's recommendations into practice. For the ordinary coal-burning cooking range, of which the comparative inefficiency and the wastefulness, both in fuel and labour, are recognized by many householders as well as by the experts who gave evidence before the Commission, the substitution of a gas-cooker is advocated; where gas is not available the alternative of electric cooking or ranges which burn coke or anthracite should be considered. It must be remembered that anthracite heating requires special stoves and special arrangements for ventilation; ranges designed to burn this fuel, however, are already on the market. For hot water supply the memorandum recommends the provision of means other than the boiler at the back of the open coal fire; thus the installation of a small coke-fire boiler placed in the scullery is described as satisfactory, cheap, and efficient, and it has the additional advantage of enabling a certain amount of auxiliary heating to be obtained from radiators supplied by the same boiler. For warming the living-rooms or bedrooms the provision of coke-burning grates, of gas fires, or of hot-water radiators is enjoined. Local circumstances of course differ very much, particularly as between urban and rural areas; nevertheless, so much importance is attached to the recommendations of the Departmental Committee, that in accordance therewith local authorities are asked to consider the practicability of modifying the projected heating and cooking arrangements of dwellings which have not yet been completed. As was

THE Registrar of the General Medical Council informs us that by an Order in Council dated December 21st, 1920, since the Kingdom of Belgium no longer affords to the medical practitioners of the United Kingdom such privileges of practising in Belgium as were offered during the late war, His Majesty has ordered that the Order in Council of January 7th, 1915, be revoked without prejudice to the right of any persons whose names have already been registered. Persons possessing Belgian qualifications are therefore no longer entitled to registration in the *Medical Register* of the United Kingdom.

Six Hunterian lectures on the Principles of Human Craniology, illustrated by specimens and preparations, will be delivered by Professor Arthur Keith in the theatre of the Royal College of Surgeons of England in Lincoln's Inn Fields at 5 o'clock on January 17th, 19th, 21st, 24th, 26th, and 28th.

NEW YEAR HONOURS.

THE New Year Honours announced on January 1st include awards to the following members of the medical profession:

Knighthood.

DAWSON WILLIAMS, C.B.E., M.D., D.Sc., F.R.C.P., Editor of the *British Medical Journal*.

S. SQUIRE SPRIGGE, M.A., M.D., Editor of the *Lancet*.

CHARLES RYALL, C.B.E., F.R.C.S., Senior Surgeon to the Cancer Hospital and to the Bolingbroke Hospital.

WILLIAM HODGSON, L.R.C.P.I., L.R.F.P.S.Glasg. For public services in Crewe.

EDWARD COEY BIGGER, M.D., M.Ch., Chairman of the Irish Public Health Council and Medical Member of Local Government Board, Ireland.

ALFVANDER JARVIE HOOD, M.B., C.M., Senior Honorary Physician, Prince of Wales's (Military) Hospital, Randwick, New South Wales.

K.C.B. (Military Division).

MAJOR-GENERAL ROBERT PORTER, C.B., C.M.G., M.B., Army Medical Service (ret. pay).

K.C.V.O.

FREDERICK STANLEY HEWETT, M.V.O., M.D., Surgeon-Apothecary to the King and His Majesty's Household; and to Queen Alexandra and Her Majesty's Household.

C.V.O.

WILLIAM FAIRBANK, M.V.O., O.B.E., Surgeon in Ordinary to His Majesty's Household, Windsor Castle.

C.M.G.

EDWARD CHARLES LONG, Principal Medical Officer, Basutoland.

THOMAS EDMUND RICE, Director of the Medical and Sanitary Services, Nigeria, formerly P.M.O. Sierra Leone and the Gold Coast.

C.I.E.

LIEUT. COLONEL DAVID MACDONALD DAVIDSON, I.M.S., Civil Surgeon, Lahore, Punjab.

LIEUT. COLONEL FREDERICK O'KINLEY, I.M.S., Surgeon Superintendent, Presidency General Hospital, Calcutta, Bengal.

LIEUT. COLONEL WILLIAM FREDERICK HARVEY, I.M.S., Director, Central Research Institute, Kasauli, Punjab.

LIEUT. COLONEL JOHN LAWRENCE VAN GEYZEL, late I.M.S., Examiner of Medical Stores, India Store Depot.

Kaisar-i-Hind Medal.

A Kaisar-i Hind Medal, for public services in India of the first class, has been awarded to Miss Annette Matilda Benson, M.D., B.Sc., formerly senior physician, Cama and Albless Hospitals, Bombay.

Surgeon Commander Christopher L. W. Bunton, R.N., has been promoted to the rank of Surgeon Captain.

A *Knighthood* has been conferred on Mr. P. J. Michelli, C.M.G., Secretary to the London School of Tropical Medicine, and the *C.I.E.* on Dr. Edwin John Butler, Imperial Mycologist, Pisa.

Medical Notes in Parliament.

Vaccination.

In reply to Mr. Swan, who asked whether there was anything in the Vaccination Acts or Orders issued thereunder to prevent the performance of the operation of vaccination by registered medical practitioners, other than public vaccinators, with humanized lymph, and the performance of the operation by unregistered persons, Dr. Addison said that the answer was in the negative, but the Acts provided that the certificate of successful vaccination could only be given by a registered medical practitioner. In answer to a question by Mr. Tras Wilson as to the supply of vaccine, Dr. Addison said that in addition to the Government lymph establishment, which manufactured vaccine lymph for the supply only to public vaccinators and medical officers of health, there were four private firms in England and Wales which manufactured lymph for sale. He had no jurisdiction over the private manufacture of vaccine lymph, but as regards the Government lymph establishment, all possible precautions were adopted to secure that the lymph was produced under the best conditions and was free from contamination.

In reply to Mr. Kenyon, on December 21st, Dr. Addison gave the following statement as to public vaccinations carried out in England and Wales during the past ten years and the expenditure involved:

Year.	No. of Successful Vaccinations and Revaccinations Performed by Public Vaccinators at the Cost of the Rates	Approximate Expenditure incurred in respect of Public Vaccination.	
		Expenditure out of Local Rates.	Expenditure out of Exchequer Funds.
1909-1910	415,718	£ 163,000	£ 25,000
1910-1911	394,338	174,000	30,000
1911-1912	362,757	165,000	23,000
1912-1913	334,520	158,000	19,000
1913-1914	315,067	152,000	16,000
1914-1915	—	144,000	25,000
1915-1916	—	138,000	12,000
1916-1917	—	129,000	16,000
1917-1918	232,648	116,000	21,000
1918-1919	202,913	110,000	20,000

Ex Service Men in Asylums.—In answer to Mr. Lyle, on December 21st, 1920, Mr. Macpherson said that ex service men confined in asylums and suffering from certifiable insanity due to war service were by special arrangements treated as Service patients with all the privileges of private patients. Their number on December 9th, 1920, was 5,634. The entire cost of their maintenance and treatment was borne by the Pensions Department, and treatment allowances were made on substantially the same basis as in other cases of inpatient treatment.

Lunary Certificate.—Mr. F. Roberts asked, on December 23rd, 1920, what became of the original reception order and accompanying medical certificate of inmates of asylums who were dead or who had been discharged; and whether, as some issue might turn upon the integrity and security of the original document, he would take steps to secure that the originals should remain henceforth in the custody of the Lunacy Board, and be free from the interference with their contents. Dr. Addison replied that the original addresses on papers relating to dead or discharged patients were retained by the authorities of institutions for as long as, in their discretion, they thought necessary.

Divisional and Full-time Health Insurance Officers.—Sir A. Holbrook, on December 23rd, asked the salaries to be paid to the four divisional medical officers and the thirty-three whole-time outdoor medical officers recently appointed by the Minister of Health, and what he estimated would be their travelling expenses; what expenditure would be incurred for the clerical and nursing staffs to these officers; what payment had been sanctioned for rent and care of regional offices throughout the country; whether the Minister was aware that the appointment of these officers to supervise and direct panel doctors throughout the country was strongly resented by the medical profession; and whether in view of the expense he would reconsider his decision. Dr. Addison replied that the salary to be paid to the four divisional medical officers was at the rate of £1,600 a year and for the thirty-three whole-time medical officers the salaries ranged from £1,000 to £1,400 a year, in all cases inclusive, and providing that no additional payment was to be paid in the shape of war bonus. The total travelling expenses of this staff for a full year was estimated at £8,000. In addition a clerk had been assigned in certain areas, and the cost of clerical assistance under this head was estimated at £2,700 a year. Where necessary nurses were employed to assist these medical officers at a fee of half a guinea a session. Where it had been necessary to rent premises for this work the arrangements had been made by the Office of Works. He was certainly not aware that the policy adopted was strongly resented by the medical profession. This policy, which was approved by Parliament in 1914, had been continuously supported by medical men and by the approved societies; it was sound in itself and would produce results abundantly justifying the expenditure, in the saving of health, and of the amounts paid in sickness benefit.

THE Lettsomian Lectures before the Medical Society of London will be delivered at 9 p.m. on February 7th, February 21st, and March 7th, by Mr. G. E. Gask; their subject this year is "Surgery of the lung and pleura." On Monday next, January 10th, there will be a pathological meeting; on January 24th papers will be read by Dr. Anthony Feilding and Dr. F. J. Crookshank. On February 14th a discussion on skin disease and its relation to internal disorder will be introduced by Sir James Gallo-way. On February 28th Dr. J. H. Ryffel will open a discussion on "The chemical estimation of gastric function," and on March 14th Sir Henry Gauvain will open a discussion on the "Non-operative treatment of surgical tuberculosis." The annual dinner is fixed for March 8th at the Wharfedale Rooms, Hotel Great Central. The second general meeting of the session will be held at 8 p.m. on May 23rd, at 9 o'clock the annual oration will be delivered by Lord Dawson of Penn, and this will be followed by a conversazione.

Scotland.

MR. D. M. GREIG OF DUNDEE.

Mr. D. M. GREIG, F.R.C.S.Ed., who had been thirty years in Dundee, and was senior honorary surgeon to the Royal Infirmary, has just taken up duty as Conservator of the Museum of the Royal College of Surgeons in Edinburgh. At the close of the year a pleasant function was organized by the Presidents of the Forfarshire Medical Association and the Dundee Branch of the British Medical Association, when Professor Stalker, as spokesman of his colleagues, presented Mr. Greig with a cheque subscribed in token of their appreciation of his services to the profession, and of congratulation on his appointment to a post so congenial. On December 31st the Freedom of the City was conferred on Mr. Greig in recognition of his distinguished service to the public. This is the highest honour which the municipality can give to any one who is not of its own body, and though in modern times it has usually been confined to Premiers or others achieving eminence in a similar way, those who have known the qualities and range of Mr. Greig's work best appreciate the appropriateness of the distinction. In acknowledging the honour Mr. Greig spoke of the enormous increase in the number of operations now undertaken by surgeons. When he was a student, he said, there were in the Dundee Infirmary from eighty to ninety operations a year, whereas in a recent year he had himself done over 2,000 operations. The conferring of the freedom was made the occasion of a further tribute: valuable gifts were presented to Mr. Greig, his wife, and daughter. Mr. Greig's museum, known to some who had the opportunity of seeing it as a whole and by the specimens he produced from it to illustrate his teaching, is almost unique among modern private museums. It expresses, among other fine elements, an interest in craniology, persistent and active, from the time, more than thirty years ago, when Mr. Greig was first to recognize congenital parietal perforation in the living, till to day, when it numbers some three hundred skulls individually documented. The new post will give Mr. Greig scope for his skill as a conservator, and also time—which practice denied—for literary treatment of the valuable material known to be available in Mr. Greig's case records.

WAR LESSONS IN CIVIL LIFE.

On December 15th, 1920, Sir Henry Gray of Aberdeen addressed a large meeting of the Dundee Branch of the British Medical Association on the lessons of the war and their application to civil life. The address will be published shortly in full; it was highly appreciated, and several members joined in paying a tribute of thanks to Sir Henry Gray. The meeting was followed by a dinner, under the genial chairmanship of Dr. J. S. Y. Rogers, President of the Branch.

EDINBURGH ROYAL INFIRMARY.

The report of the managers of the Royal Infirmary of Edinburgh for the twelve months ended October 1st, 1920, shows that the total number of in-patients increased from 12,550 to 13,320. The average length of treatment was 24.05 days. In addition to the cases treated in the wards, 48,117 out-patients, most of whom attended several times, received medical and surgical aid and such dressings and surgical appliances as were necessary. During the period under review there was an average waiting list of 889 persons. While the ordinary income improved, the increase was by no means in ratio to the greatly increased cost of running the hospital, while heavy arrears of work in the way of painting and so forth had accumulated during the war. The ordinary funds being quite inadequate to meet the expenditure, the managers launched a special appeal; as a result the subscriptions for the year increased by nearly £46,500 over those in 1919, and a sum of more than £60,000 was collected for the improvements and extension fund. The ordinary income during the year was £127,127. The voluntary contributions directly attributable to the organized efforts of employees now amount to some £30,000 a year. This is nearly four times the yield from that source in the year before the war. The ordinary expenditure has exceeded all previous records; it was £130,668, or more than £28,000 greater than in 1919. The cost per occupied bed increased from £115 odd to £149 odd.

Ireland.

IRISH PUBLIC HEALTH.

SIR EDWARD COEY BIGGER, M.D., Chairman of the Irish Public Health Council and medical member of the Local Government Board, has been the recipient of many congratulations from members of the medical profession and of the public service in Ireland upon the knighthood conferred upon him. He has been actively identified with the public health work in Ireland since he commenced his career as a medical practitioner in 1883 in Belfast, where his family are well known. In 1900 he was appointed Medical Inspector of the Irish Local Government Board, and was a member of the Commission on Poor Law Reform. On the retirement of Sir Thomas Stafford, he was appointed Medical Commissioner of the Local Government Board. In June, 1919, he was made Chairman of the Irish Public Health Council, which was formed in connexion with the Ministry of Health Act, 1919. Sir Edward, in a recent interview with a representative of the *Freeman's Journal*, stated that the Irish Public Health Council had recently formulated a scheme which, if adopted, would have a far-reaching effect, both in the interests of efficiency and economy in the health, hospital, medical, and veterinary services in Ireland. The scheme, however, was still before the Government, and had not been put into operation. The Council was asked to formulate proposals with a view to the submission to Parliament of an Irish Public Health Bill, which would place the public health services in Ireland on a wider and more comprehensive basis, and, where necessary, make mandatory on the local health authorities various adoptive and permissive health enactments. The Council published its report (which was practically unanimous) last May. This report was subsequently approved by a meeting of delegates fully representative of the Irish medical profession. It was also approved by the Royal College of Physicians in Ireland and other important medical bodies. The present system of medical attendance upon the sick poor, established under the Medical Charities Act of 1851, ensured that no poor persons need be without free medical attendance and the necessary medicine when they were sick. That system of medical relief fulfilled a very useful purpose, but to meet more modern conditions it required to be wholly reorganized. It should, in his opinion, be completely separated from the Poor Law administration and remodelled with a view to removing any possibilities of abuse. The local area of control should be extended from the union to the county, and the system linked up with a general county public health, medical, and hospital scheme. Sir Edward said that the Irish Public Health Council had recommended that a system of medical treatment should be provided as part of a general hospital system under the control of county health boards: (1) for insured persons on a contributory basis; and (2) for those who are admittedly unable to contribute. Drastic reforms were recommended for improving the conditions under which members of the medical profession would be called upon to carry out the treatment of the classes referred to. The hospitals in Ireland were under the control of various bodies, none of them public health authorities; they should be under the control of the sanitary authority, whose duty it is to prevent the spread of infection. The lunatic asylums were administered by separate committees. Co-ordination was not only required in hospital administration, but there was a great necessity for a simplification and a unification of the mode of administration of local and special hospitals. One of the most important and essential conditions of the public health services, Sir Edward Coey Bigger urged, was the appointment of county medical officers of health, and the transference of all health administration to the county health authority.

THE HENRY MOORE MEMORIAL.

Friends of the late Lieut.-Colonel Henry Moore, who died of wounds while on service in France, resolved that the memorial they wished to raise to his memory would best be established in connexion with the City of Dublin Hospital, to which he was surgeon for twenty-two years. At a gathering of the subscribers at the hospital the

memorial was formally presented and accepted by Dr. G. Jameson Johnston, the senior surgeon. It consisted of a brass tablet and a sum of £700 for a male bed and a child's cot. The tablet, which has been erected in the entrance hall, bears the following inscription:

In memory of Lieut.-Colonel Henry Moore, D.S.O., M.C., Surgeon to the Royal City of Dublin Hospital, 1896-1918. This Tablet, together with Memorial Beds, has been instituted by a number of those who desire to preserve his name as a zealous worker in the interests of the Hospital, and a man truly devoted to his profession. Kindly to all, and a friend of many, he served in the Great War from Mons until his death, at Wimereux, from wounds received in the discharge of his duty, on the 29th May, 1918.

County Court Judge Pigot, who made the presentation, recalled that Lieut.-Colonel Moore had served during the South African campaign as well as for four years during the Great War.

England and Wales.

THE L.C.C. AND THE TRAINING OF PUPIL MIDWIVES.

THE Ministry of Health, in a recent communication to the Central Midwives Board, offered to arrange for the women medical officers and nurse inspectors on the staff of the Ministry to inspect and advise the Board upon midwives or institutions desirous of obtaining the Board's sanction to undertake the training of pupil midwives. This is a service which has been undertaken under the Midwives Acts by the officers of the London County Council who are qualified women medical practitioners in conjunction with their ordinary duties, and as the Ministry's offer indicated the possibility of overlapping, the London County Council communicated with the Ministry. The reply, read at the meeting of the Council on December 14th, repeated that the offer had been made, but that it rested with the Central Midwives Board to decide in each case whether it would ask for a report from the officer of the local supervising authority or from an officer of the Ministry. The Ministry's reply was regarded as unsatisfactory by the Midwives Acts Committee of the Council, who stated that there was no reason to suppose that the Board was dissatisfied with the assistance rendered by the Council's inspectors in the matter, and the Council recorded its opinion that the action of the Ministry was unnecessary, would lead to confusion, and would involve a wasteful employment of staff. The Minister is to be asked to receive a deputation on the subject.

BRISTOL MEDICAL SCHOOL.

The guest of the evening at the annual dinner of the Medical School of the University of Bristol, held under the presidency of Dr. George Parker, was Sir Robert Jones, K.B.E. Dr. C. Ferrier Walters, surgeon to the Bristol Royal Infirmary, in proposing his health, said that Sir Robert's mission in life had been the improvement, correction, and cure of those ill, diseases, and deformities which man had reaped by his neglect of nature, by his ignorance, his carelessness, or his misfortune. His had been the leading part in the organization of the magnificent orthopaedic hospitals, through which thousands of wounded men had returned to civil life. Thus, after long years, he had come into his own. Mr. Walters also referred to Sir Robert's goodness to the younger men and his extraordinary interest in their work. Sir Robert Jones, in reply, recounted some of his early experiences in endeavouring to induce the War Office to form an orthopaedic department in the army. He concluded by proposing the toast of "The Medical School and University." In Sir Isambard Owen, who had done so much to build up its reputation, the university had, he said, a medical and scientific vice-chancellor who had rendered it great services. Professor Fawcett, dean of the school, in response, compared the magnificent quarters now occupied by the school with the buildings when he first joined it twenty-seven years ago. Bristol had become the envy of other universities. This was due largely to the generosity of the Wills family; but more had to be done, for all lecturers ought to be paid, and there should be endowed scholarships for research open to young graduates. No other school could offer better facilities for clinical work

than Bristol, and it might be added that it held a remarkable position as regards games, both cricket and football. Professor Tyndall, replying for the science faculty, expressed the hope that there would in future be more co-operation between medical men and chemists and physicists. Mr. Richardson Cross proposed the toast of "The Past and Present Students," which was acknowledged by Dr. D. T. Price, Miss Golding, and Mr. G. Bush.

Australia.

PROFESSORSHIP OF ANATOMY AT SYDNEY UNIVERSITY.

THE Senate of Sydney University has decided to appoint a full professor of anatomy, in succession to Professor J. T. Wilson, who now occupies the chair of anatomy at Cambridge, and also an associate professor. This division of the chair has become necessary in consequence of the large number of medical students now passing through the medical school. The position of associate professor has been filled by the appointment of a Sydney graduate, Dr. John I. Hunter, who has been a demonstrator in the Department of Anatomy for several years. He was born in Victoria in 1898, and is thus only 22 years of age. After a public school education he entered the Sydney University with a bursary in 1915. He had a brilliant career, and graduated M.B., Ch.M. last March. He has proved his ability as a teacher and demonstrator, and has given proof of ability in original research. Few who know Dr. Hunter are surprised at his appointment, for great things have always been expected of him.

THE INFLUENZA EPIDEMIC IN WESTERN AUSTRALIA.

The influenza epidemic in 1919 caused the death rate in Western Australia to rise from 9.1 to 11.1. In his report for the two years ending December 31st, 1919, Dr. R. C. Everitt Atkinson, commissioner of public health and principal medical officer, describes how the State authorities, warned by the devastating outbreak in New Zealand, were able to formulate measures of quarantine, isolation, and inoculation for combating the spread of influenza if the epidemic should reach Western Australia. After influenza had been notified from Victoria in January, 1919, quarantine was instituted at points of communication both by land and by sea. Unfortunately the quarantine arrangements led in both instances to considerable friction with the Commonwealth authorities; the trouble seems to have been due, on the one hand, to the commandeering of railway travelling stock as quarantine stations and on the other, to disagreement as to the period of quarantine necessary for sea travellers. It is believed that by the institution of quarantine the introduction of infection was delayed and its virulence diminished; in the early days of June, however, an outbreak of fifty-seven cases occurred at Gwalia, and spread in spite of a locally instituted quarantine, to other districts. Perth was infected on June 6th, and the last area to be reached was Broome (November 25th). Clinically the infection resembled that occurring annually in the state, save for the greater subsequent prostration and the frequency of serious lung complications. Haemorrhages from the nose, pharynx, bowel, bladder, and uterus were common; abortion was frequent in pregnant women, of whom many died. Syphilis did extremely badly; the same was observed of chronic alcoholics, but moderate drinkers, it is stated, seemed to have some immunity. In males the greatest number of deaths occurred between the ages of 30 and 35, and in females between 25 and 30; twice as many males died from influenza as females. Nearly 100,000 inoculations were given at public depôts and at public expense; although no properly controlled evidence is available as to the value of this measure, the majority of practitioners thought it afforded a considerable degree of protection against the more serious complications.

MESSRS. JOHN BALE, SONS, AND DANIELSSON, LTD., inform us that they have recently published English editions of Drs. Cruchet and Moulinier's book on Air Sickness, and of Drs. Maublanc and Ratié's book on Medical Examination of Airmen, reviewed in our last issue at p. 18.

Correspondence.

THE STUDY OF HEART DISEASE.

SIR,—In his valuable lecture on "The Study of Heart Disease" (BRITISH MEDICAL JOURNAL, December 11th, 1920) Dr. Poynton regrets that the possibilities of methods of prevention "have not been fully explored"; and he asks, in relation to the responsibilities of rheumatism as a cause of cardiac lesions, "Is the general public sufficiently alive to the danger of this disease?" Practitioners who have had much experience in children's hospitals will, I imagine, agree with the negative implied in this question. The public is not alive to the danger, and this largely because to the public rheumatism means pain, and particularly pain in the joints. If this ignorance is to be dispelled the end can only be attained by the action of the medical profession. On several occasions during the last twenty years I have urged that the discovery of rheumatism in any of its manifestations in any member of a family ought to be the occasion for warning parents that any slight illness in one or other of their children probably carries the risk of heart disease, and that the only chance of protection is early and complete rest in bed. Not until this warning is a universal policy can it be said that the medical profession has taken all possible steps for the prevention of heart disease in early life.

Dr. Poynton recognizes that heart disease "as we see it in our hospitals is infrequent in the well-to-do," and suggests that this experience prompts "careful systematic inquiry into housing and clothing and school influences." Is it not probable that, without minimizing the agencies he proposes, an explanation of the contrast may be that in the richer classes of the community even apparently slight and trivial symptoms secure prompt rest in bed, while among the poorer classes this precaution is neglected or postponed? It will continue to be neglected or postponed until parents are systematically told that the mischief that has fallen on one of their children may be repeated in others unless rest is practised from the outset even of minor disturbances and complaints.

Everyone must admire Dr. Poynton's persevering efforts to ensure a thorough knowledge of rheumatism in early life in the medical profession, and must sympathize with his desire for "special arrangements for cases of early heart disease to have a long period of rest." But still more desirable is it to secure the rest at a date when prevention, not mere amelioration, is at least possible. This will be obtained only when, rheumatism in one or other of its forms having appeared in a family, the parents learn from their medical advisers the actual risks which their children run. Other preventive agencies may perchance in time be discovered. But for the present we know of none but early and complete rest. It is for the profession to consider whether this knowledge is in practice applied as widely as it ought to be.—I am, etc.,

London, W., Dec. 28th, 1920.

C. O. HAWTHORNE.

THE MINISTRY OF HEALTH AND THE PROFESSION.

SIR,—In last week's issue of the JOURNAL Dr. Brackenbury hints rather vaguely that—

"A section of the lay press, certain politicians, lay administrators, and political wirepullers, influenced mainly by the tactics of party warfare, are attempting to undermine the position and machinery of the Ministry of Health";

and he urges our profession to come to the rescue.

It is to be hoped that we will do no such thing. As a profession and in our Association—as Dr. Brackenbury recognizes—we have no concern with politics and its many underhand ways. No doubt the very naughty conspiracies he refers to will meet in due time with their historic punishment. What can we know of the currents and cross-currents now seemingly at work; how can we possibly, therefore, steer a correct course if we launch out into the deep?

Is it not possible that, as our profession for the first time is being drawn from its traditional retirement into closer touch with the political world, therefore becoming able to look down into the arena of political strife, many of us

feel that if there is to be any fighting we would wish to be there? But it must not be. Deliberate, individual partisan action on behalf of the present Ministry of Health—as quite recently shown in the *Times* by those at the moment recognized in our profession and Association as amongst its "leaders"—only breeds distrust and suspicion in the profession and also in politicians of all schools; thereby helping to defeat ultimately the very objects which we all have in view. The lack of restraint shown is to be deplored.

It is not for our profession nor the Association officially without due consideration and approval to take up the cudgels on behalf of any Ministry. Sufficient it should be for us to express our opinion on questions affecting health in plain and unmistakable language, and then to proceed to organize ourselves and public opinion in support of the same.

Our profession has spoken out on many recent occasions, and no doubt is prepared to do so again directly an opportunity occurs. Until then let us retain our detached position, and leave the political arena and its subterranean passages to those who seemingly consider life therein to be as the breath to their nostrils.

We must not forget the sorry plight of the peacemaker who ventured to interfere in a family discussion.—I am, etc.,

Hove, Jan. 3rd.

E. ROWLAND FOTHERGILL.

THE BEGINNINGS OF LIFE.

SIR,—I have read with much interest the leading article in your issue of December 25th, 1920, on "The Beginnings of Life." As a firm believer in the doctrines of my father, the late Dr. Charlton Bastian, F.R.S., I am specially interested in the new researches of Professor Benjamin Moore, F.R.S., and his co-workers on sunlight and the life of the sea.

I must demur, however, to a statement in your concluding paragraph. You say:

"It would seem that inquiries conducted along these lines into the functions of marine and fresh-water algae are more likely to bring us towards a solution of the origin of life than investigations directed to bacteria and fungi, which can exist only upon organic matter, whereas the primordial world could contain no such matter before the advent of life."

I would like to ask what is the authority for stating that bacteria and fungi can exist "only upon organic matter" and has this been definitely proved or disproved? In this connexion I would refer your readers to a short article entitled "The Simplest Kind of Protoplasm," to be found as an appendix to Dr. Bastian's small book, *The Nature and Origin of Living Matter* (Watts and Co., R.P.A. Cheap Reprints, No. 41).—I am, etc.,

W. BASTIAN,

Portsmouth, Dec. 27th, 1920.

Surgeon Commander R.N.

SIR,—I am interested to observe that the opinions of Professor Stanley Gardiner, Professor B. Moore, and others, as reported in your leading article, "The Beginnings of Life," in the JOURNAL of December 25th, 1920, p. 982, coincide with my own, as published twenty-one years ago.

In a paper entitled "What is Life?" read before the Birmingham Natural History and Philosophical Society on February 21st, 1899, and published in the *Proceedings* of that society for the same year, I advocated the theory that the "lability" of living substance is fundamentally due to the changeability of nitrogen compounds, and that nitrogen is the central element in all those chemical reactions which we regard as peculiarly vital.

Discussing the origin of life, the paper proceeds (pp. 61-63):

"Both our speculation and our experiments should be based on the assumption (in the absence of evidence to the contrary) that life is the same in its essence nowadays as when it first dawned on the earth; that the transition from inert to living matter is now going on by the same essential reactions as at all times, only that as the result of evolution the apparatus for the performance of these reactions has become highly specialized.

"Provisionally, then, I imagine some such reactions as the following to have occurred: that solar energy, acting on the water or damp earth containing the raw materials before mentioned (ammonia, oxides of nitrogen, CO₂, and the usual

salts, such as chlorides, sulphates, and phosphates of Na, K, Ca, Mg, Fe,] caused dissociation and rearrangement of the atoms; that the nitrogen abstracted oxygen from its compounds with carbon, hydrogen, sulphur (phosphorus?), and other elements and delivered it to the atmosphere. Not much energy would be absorbed by a transparent liquid; such actions as the above would occur rather in water containing compounds of iron in solution or suspension. These compounds would absorb the solar energy, and the iron itself would assist in carrying oxygen hither or thither; and hence possibly iron was as intimately concerned in the first glimmer of life in the past as in its mightiest flame to-day.

"In this way compounds of nitrogen, carbon, etc., would accumulate in the water or damp earth; and further reactions, anabolic and catabolic, would occur among them by virtue of the lability of the nitrogen compounds. Life at this stage would be of the humblest kind; we should hardly recognize it as life nowadays. There would be no definite organisms—only, diffuse substances trading in energy. Between this stage and the evolution of cellular organisms an immense period may have elapsed, and that period may have witnessed many intermediate stages. The development of the cell form in living beings must have marked a most important epoch in the history of life.

"It may be a debatable question whether the earliest organisms were able to utilize the energy of sunshine or whether their whole energy was derived from the N compounds produced in the atmosphere by lightning. But in any case the faculty of appropriating the energy of sunshine must have developed early, if not at the very beginning. In the functions of life anabolism precedes catabolism; and one would therefore suppose that the earliest forms of life were concerned more in accumulating than in dispersing energy, and therefore that the energy-dispersing organisms, like bacteria and fungi, may have had a comparatively late origin. . . .

"I imagine that [nitrogen appropriating bacteria, growing on the roots of leguminous plants] cannot represent an early form of life or an early source of combined nitrogen. This assimilation of nitrogen is an anabolic process; but the energy for its performance is obtained, not from sunshine, but by combustion of carbon and hydrogen compounds which the said organisms absorb from the soil. The total result of the process is therefore a dispersion of the energy which other organisms had previously accumulated.

"Life implies that the first attempts at it would begin. Why, then, do we not find evidence of these processes in the shape of primitive vital substances in water or elsewhere? The answer is not far to seek. If any such substances begin to be formed, they are seized and assimilated by the already developed organisms. Experience teaches us that this must be so. We know that compounds of nitrogen, oxygen, carbon, hydrogen, sulphur, and phosphorus, which we make in the laboratory, are inconveniently prone to be attacked by lowly organisms."

—I am, etc.,

Cambridge, Jan 1st.

F. J. ALLEN.

BRITISH AID FOR MEN OF LETTERS AND SCIENCE IN RUSSIA.

SIR,—We have recently been able to get some direct communication from men of science and men of letters in North Russia. Their condition is one of great privation and limitation. They share in the consequences of the almost complete economic exhaustion of Russia; like most people in that country they are ill-clad, underfed, and short of such physical necessities as make life tolerable.

Nevertheless a certain amount of scientific research and some literary work still goes on. The Bolsheviks were at first regardless and even in some cases hostile to these intellectual workers, but the Bolshevik Government has apparently come to realize something of the importance of scientific and literary work to the community, and the remnant—for deaths among them have been very numerous—the remnant of these people, the flower of the mental life of Russia, has now been gathered together into two special rationing organizations, which ensure at least the bare necessities of life for them.

These organizations have their headquarters in two buildings known as the House of Science and the House of Literature and Art. Under the former we note such great names as those of Pavlov the physiologist and Nobel prize-man, Karpinsky the geologist, Borodin the botanist, Belopolsky the astronomer, Tagantzer the criminologist, Oldenburg the orientalist and permanent secretary of the Petrograd Academy of Science, Koni, Bechterev, Latishver, Morozov, and many others familiar to the whole scientific world.

Several of these scientific men have been interviewed and affairs discussed with them, particularly as to whether anything could be done to help them. There were many

matters in which it would be possible to assist them, but upon one in particular they laid stress. Their thought and work is greatly impeded by the fact that they have seen practically no European books or publications since the revolution. This is an inconvenience amounting to real intellectual distress. In the hope that this condition may be relieved by an appeal to British scientific workers Professor Oldenburg formed a small committee and made a comprehensive list of books and publications needed by the intellectual community in Russia if it is to keep alive and abreast of the rest of the world.

It is, of course, necessary to be assured that any aid of this kind provided for literary and scientific men in Russia would reach its destination. The Bolshevik Government in Moscow, the Russian trade delegations in Reval and London, and our own authorities have therefore been consulted, and it would appear that there will be no obstacles to the transmission of this needed material to the House of Science and the House of Literature and Art. It can be got through by special facilities even under present conditions.

Many of the publications named in the Oldenburg list will have to be bought, the costs of transmission will be considerable, and accordingly, the undersigned have formed themselves into a small committee for the collection and administration of a fund for the supply of scientific and literary publications, and possibly, if the amount subscribed permits of it, of other necessities, to these Russian savants and men of letters.

We hope to work in close association with the Royal Society and other leading learned societies in this matter. The British Science Guild has kindly granted the Committee permission to use its address.

We appeal for subscriptions, and ask that cheques should be made out to the treasurer, C. Hagberg Wright, LL.D., and sent to the British Committee for Aiding Men of Letters and Science in Russia, British Science Guild offices, 6, John Street, Adelphi, London, W.C.2.—We are, etc.,

THE RISKS AFTER OPERATIONS FOR TONSILS AND ADENOIDS IN OUTDOOR CLINICS.

SIR,—The profession and the public, no less than laryngologists, should be grateful to Mr. Eric Watson-Williams for his timely article in your issue of December 11th, 1920, in which he deals with the risks run by patients who are sent to their homes within an hour or two of the operation for the removal of tonsils and adenoids in out-patient clinics.

It is a subject which has long vexed those who have charge of these operations, and its solution seems still to be far off, because the beds allotted to the ear and throat departments of our hospitals, general and special, are few, and they are always filled by what are termed "urgent" cases, which demand major operative procedures. For these beds there is always a long waiting list, and hence the "tonsils and adenoids" have to be dealt with as out-patients, and for the present I can see no likelihood that beds will be provided for them so that they can be admitted as in-patients even for forty eight hours.

Finding myself face to face with the insuperable difficulty outlined above, and experiencing the occasional complications which Mr. E. Watson-Williams has so clearly outlined in his communication, I adopted the plan of having the following printed directions given to the patients or their parents in the hope that we might reduce accidents to a minimum.

UNIVERSITY COLLEGE HOSPITAL, EAR, NOSE AND THROAT DEPARTMENT.

Directions for the Care of Patients Before and After the Removal of Tonsils and Adenoids.

1. At 6.30 to 7 o'clock on the morning of the day of operation give the child a light breakfast of thin bread and butter and a cup of weak tea, but after that give him nothing whatever either to eat or drink. The patient should be at the hospital at 9 a.m.
2. A parent or responsible adult must come with the patient. Please bring a wrap to travel in and also a clean towel.

3. After the operation, and when you are told the child may be removed, take him straight home, put him to bed and keep him there for two days. Give him nothing to eat or drink for at least four hours after the operation, then he may have a little warm milk, beef-tea, bovril, or weak tea, and in the evening a small basin of bread and milk.

4. On the day after the operation he may have any soft food to which he is accustomed.

5. During the first twelve hours following on the operation he may be sick and bring up some blood which has been swallowed, but if he bleeds from the nose or mouth without vomiting, give teaspoonfuls of iced water every two or three minutes for an hour. Should this fail to check the bleeding bring the child to the hospital or send for the nearest doctor.

6. Keep the child indoors for four days after the operation and avoid exposing him to bad smells and infection from people suffering from fever of any kind or from "a cold in the head."

7. Patients operated upon should attend the following week for examination.

These directions have been in use in my department for some fifteen years, and I have no shadow of doubt that they have had an excellent effect in reducing the number of avoidable complications after the removal of tonsils and adenoids.

It is in the hope that such "directions" may be useful to others that I have asked for them to be printed with this note. Incidentally I should like to add that:

1. No patient is operated upon as an out-patient unless he lives within a radius of three to four miles from the hospital. Beyond such a distance the patient waits his turn for admission as an in-patient, and is kept for at least forty-eight hours.

2. All tonsils are enucleated by one of the many methods employed for that operation.

3. No patient is allowed to leave the operating table until the tonsillar recesses have ceased to bleed. The majority of the cases of so-called "secondary haemorrhage" are really continued haemorrhage—that is, bleeding which was not checked at the time of operation.

4. Each patient is kept at rest in suitable cubicles for three to four hours before he returns to his home.

Under no consideration would I consent to operate on a patient in my own house and send him (or her) home in a car or carriage.—I am, etc.,

HERBERT TILLEY,

Surgeon, Ear and Throat Department,
University College Hospital, London.

London, W., Dec. 26th, 1920.

SIR,—I am much interested in the letters which have appeared recently in the JOURNAL on the above subject. That it is time that something is done in the matter there can be no doubt.

In this hospital no case is allowed to leave after operation if there is any sign of distress or of haemorrhage. The parent is warned to put the child to bed on arrival home and not to allow it out of doors for two days in the winter time. If there are any active conditions which are due to the presence of the tonsils and adenoids the case is taken into the hospital.

Sir William Milligan's remarks as to operations in consulting rooms are only too true. Until the public realize that the practised surgeon is the proper person to perform operations, I fear the consulting room will still continue to be used in this unwarranted manner.—I am, etc.,

J. A. GIBB,

Surgeon, Kent County Ophthalmic Hospital for
Diseases of the Eye, Ear, Nose and Throat.

Maidstone, Dec. 26th, 1920.

THE CONFERENCE ON VOLUNTARY HOSPITALS.

SIR,—I was greatly interested in your report of this conference. This is how it struck me:

Mr. Bishop Harman moved a resolution "of belief that the voluntary method of maintenance and staffing of the voluntary hospitals of the country is to the advantage of the public, of medical science, and of the medical profession." He only expressed pious opinions. He said, "Freedom was a necessary condition to the gathering of the best fruits of medical experience and practice." Freedom from what? Supposing the hospitals were State supported, and managed by a committee partly elected and partly co-opted, such as the Insurance Committee, what freedom would be lost? Let him answer. He yearned for charitable hospitals and necessitous patients, and doctors receiving no direct monetary emolument. He forgets that citizens want citizen hospitals, desire their doctors to be adequately paid, and the work done to be as efficient and up-to-date as possible. He suggested that it would be a distinct loss to the wealthy if they had no "charitable objects" to patronize.

Sir Henry Davy wanted a wage limit for patients, with its accompanying inquiries. His idea seemed to be turning the voluntary hospitals into charitable nursing homes, to be run by the doctors and the dispensers of charity, not without profit to the doctors. I would like to ask Sir Hamilton Ballance to state his reasons why the doctors should not be paid for services rendered. Dr. W. S. Dickie is only anxious that the doctors should not be paid.

Dr. Astley Clarke said the primary meaning of a voluntary hospital system was a system free from bureaucracy. What objection has he to a citizens' hospital, to which every citizen would have the right of admission, in which the doctors might be adequately paid for their work, and the majority of their committee consist of their own elected representatives?

Dr. Bolam hit the nail on the head when he said that many of the hospitals were run on the dispensary system, the only difference being that the doctors were not paid. Mr. Bishop Harman said it was because of the flavour of voluntarism that these hospitals were sought out by the State or municipality to perform special services—for example, the treatment of venereal disease. Does he really believe that? Up to last year I was a town councillor. We attached the venereal clinic to the local hospital. But I never heard a word about this flavour. All the town council thought of was how to get the work done most efficiently. The equipment and conveniences were at the local hospital, and so was the experienced doctor, whom they were willing to pay to do the work efficiently. Mr. Harman ingenuously confessed he could not defend voluntarism on logical grounds. He moved a resolution in favour of accepting State contributions, without any proportional control. Is he aware that this is the age of democracy?

May I also suggest that, as was discovered in Wigan, if the workers practically find the income for the hospital they will demand proportionate control? If the insurance companies do the same they will make the same demand. I may say that it was found impossible to establish a system of almoners in Wigan; the working man will not have it. Then the question arises, if money is to be paid by Insurance Committees, are they to be adequately represented on the boards of management? Then, finally, let me ask, in the words of Mr. A. E. Morison, why should it remain in existence—"that the only charitable part of the undertaking was the work of the medical and nursing staff"? Will some of the leaders of the profession at the meeting enlighten the public on this curious point: Why does the medical profession desire to do the staffing of hospitals without remuneration?—I am, etc.,

FREDERICK REES, M.D.,

Honorary Consulting Physician, Royal Albert
Edward Infirmary, Wigan.

January 3rd.

VENEREAL DISEASE PROPHYLAXIS.

SIR,—Though loath to intervene in the correspondence on the prophylaxis of venereal diseases, I feel that Dr. Bayly's letter in your issue of January 1st calls for a brief comment.

He appears to misunderstand completely the ethical objection to the propaganda of the Society for the Prevention of Venereal Disease. It is this—that the broadcast issue of their instructions implies a sanction to immorality on the part of the community, and that the logical issue of their teaching, namely, the constant carrying of a prophylactic outfit, must act as a continuous incitement to seek opportunities for its use.

But apart from this ethical objection there is the practical one, that the balance of available evidence is against the efficacy of this form of prophylaxis. Though official figures are not yet published, it is widely known that the incidence of venereal disease among our troops on the Rhine has reached an almost incredibly high figure. The reasons for this are doubtless complex, but the important fact from the point of view of the present controversy is this—that this has occurred in spite of the free supply to these troops of various prophylactics (including the much vaunted "permanganate") and an intensive campaign of instruction in their use.

In the face of this evidence Dr. Bayly's heroics regarding the iniquity of withholding this "scientific" knowledge from suffering mankind appear rather futile.—I am, etc.,

OTTO MAX

London, W., Jan. 1st.

SIR,—In your issue of January 1st Dr. J. Lorimer Hawthorne objects to the note by the Medical Women's Federation on self-disinfection on the grounds that it gives a wrong impression of the aims and methods of the Society for the Prevention of Venereal Disease. She suggests that the writers of the note to which she objects should have verified the accuracy of their information. That information is derived from the annual report for 1920, and from the speech of the president of the society. It is as follows:

"Therefore we are going to take every step that we can in order to ensure that all boys and girls, men and women in the United Kingdom shall have access to the latest scientific knowledge with regard to immediate self-disinfection."

Again:

"There are twelve towns which have already given instructions that the inhabitants shall be instructed in immediate self-disinfection."

Boys, girls, men, women, inhabitants!

Nothing in any of the public speeches of the agents of the Society for the Prevention of Venereal Disease, nor in their numerous communications to the press, nor in any of their published propaganda has, as far as I have seen or heard, given the public any reason to think that the aims and methods were anything other than those described by their president.

Their ideal, such as it was, appeared to be consistent. The Medical Women's Federation merely pointed out that in the case of those who most needed and deserved the promised protection—young girls and young married women—it would be almost bound to fail. Surely Dr. Hawthorne could do better in support of the organization that she champions than to characterize its aims as "unjustifiable and revolting"—for that, in effect, is what she does.

Dr. Hawthorne also considers the instruction of young boys and girls as "unjustifiable and revolting," although, mainly as a result of the work of her society, the boys of Manchester (and, for aught I know to the contrary, of other towns) can learn all that men can learn in the public lavatories.

As regards the "Directions for Women" (which the Medical Women's Federation has not yet criticized), it is interesting to learn that they should be known as "Directions for Prostitutes." Yet how, in view of the title, and in view of the presidential exposition of the society's aims, were the Medical Women's Federation to know that?

It turns out that instead of being an organization for safeguarding the young beginner, or all boys, girls, men, and women, the Society for the Prevention of Venereal Disease only proposes to apply its benefits to those who resort to prostitutes. The advertisement of its methods as new and scientific will, however, not greatly appeal to those who recognize a very old nostrum in a hardly newer setting. Nor is the public likely to wish to pay for this propaganda one moment after it understands its true meaning.

I put it to Dr. Hawthorne that the noble profession of medicine does not exist in order to fold its hands and say piously that what must be, must be. It is here, rather, to find out and to point men to what they are capable of becoming, and to the real and full enjoyment of all their instincts.

As regards the "Directions for Prostitutes," I ask Dr. Hawthorne to fix her medical imagination on a mucous surface which normally cleanses itself fairly effectively, and which tolerates greasy applications indifferently. Cover it with several layers of a very adhesive grease. Mix on this a layer of decomposing discharges and other debris. Repeat the layers several times. Imagine this in the majority of prostitutes—trained in cleanliness, care often afraid of it. Note the foul and dangerous surface that ensues. Consider this as a suitable surface for conveying "mediate" contagion. Let the patient douche herself with warm permanganate. Observe that the filthy surface is not removed thereby. Can any thinking person believe that such a "method" deserves the name of "scientific"?

Lastly, my experience is that numbers of prostitutes, amateur or professional, do have children. Some, no doubt, do away with their children, some are bad mothers, but many are cured of their abnormal habits, and

redeemed by a child. So that contraceptives are not entirely irrelevant to this question. Everyone is entitled to know the effects of drugs she is advised to use.—I am, etc.,

A MEMBER OF THE MEDICAL WOMEN'S
FEDERATION.

January 4th.

THE NAVAL MEDICAL SERVICE.

SIR,—The six medical officers are to be congratulated on their letter in the JOURNAL of December 11th, 1920. There are, however, some fundamental points to which I think it desirable to call attention in our efforts for reform.

Leadership.—The natural leader is the Director-General, but seeing that he has no seat at the Board of Admiralty the leadership must temporarily be a committee of the British Medical Association. Suitable leaders should be elected; at present very few of us know how the committee is formed. It is well known to most of us that the minor grievance in connexion with coroners' fees took seven years to settle.

Publication of the Durnford Report.—It is understood that this report contains an excellent basis of reform. An effort should be made to have it published. It could be published in the *Naval Medical Journal* without expense to the Admiralty. The ceaseless reiteration of grievances is futile. Action is the fashion of the day.

Financial.—Possibly the nation cannot bear the strain of increased allowances, as hinted at in the above mentioned letter; a solution, however, might be found in rear admirals and captains pooling their allowances with surgeon rear admirals and surgeon captains respectively.—I am, etc.,

December, 1920.

ACTION.

* The Naval and Military Committee consists of two members appointed by the Representative Body, two by the Council, together with the representatives on the Council of the Royal Naval Medical Service, the Royal Air Force Medical Service, the Army Medical Service, and the Indian Medical Service.

MUSCLE RE-EDUCATION IN INFANTILE PARALYSIS.

SIR,—In reply to Dr. Mackay's letter in your issue of December 18th, I must repeat that I am still quite unable to understand how Dr. Mackay still insists that splinting and physiological rest *per se* form an integral portion of muscle re-education; his definition of the latter commences with the words "the gradual stimulation." Splinting and physiological rest cannot be regarded as a "gradual stimulation," though they may facilitate such stimulation applied subsequently by other methods.

The proof that splinting and physiological rest are not essential for recovery from infantile paralysis is a clinical one. One knows there have been hundreds and hundreds of cases in which both legs were affected who have never sought medical aid, but who have as soon as possible—often urged by parents—tried to walk again. In nearly every case such patient, upon discovering that one leg was more useful than the other, used it more, frequently ending up by employing it almost to the entire exclusion of the other. Yet in spite of the fact that the more useful leg was doing practically double work, and that it commenced to do so within a few days of the onset of the disease, that leg was the one to make a rapid and frequently perfect recovery, while the other leg, originally the less useful one, only showed feeble signs of recovery. Now if splinting and physiological rest were essential for improvement these cases would run a different course; the leg that was at first more useful would rapidly become weaker, while the other leg would soon catch it up and progress quicker. This, however, is hardly ever the case.

Nor can I agree with Dr. Mackay's statement that any treatment not based on the principles he advocates is mainly responsible for failures with infantile paralysis. I consider that they are due to other reasons, the two chief being: (1) that a vast amount of so-called Swedish treatment is given by masseurs and others who are totally incompetent to apply it; (2) the valuable method of *nerve stimulation* by the so-called "nerve frictions" (accord^g to the methods of H. Kellgren) are to the profession as yet almost an unknown factor in mechano-therapeutics.

In any case I think that this controversy has lasted long enough. I suggest that we let theorizing alone, and that Dr. Mackay let us have his results. If they show an improvement as compared with the correctly applied genuine Swedish methods I shall be delighted to acknowledge the fact to Dr. Mackay. If they do not, doubtless he will be equally pleased to do so to me.—I am, etc.,

London, W., Dec. 18th, 1920.

EDGAR F. CYRIAX.

ANGIO-NEUROTIC OEDEMA TREATED BY INJECTIONS OF HORSE SERUM.

SIR,—Dr. T. Wood Locket's letter in your issue of December 18th, 1920, on the therapeutics of normal horse serum, prompts me to send you a note of the results of its exhibition in a case of angio-neurotic oedema which lately came under my care.

The patient, a coal-dealer, had previously been seen by my partner and also by a neighbouring practitioner, and had had, I believe, six attacks. One of these was so severe, and the tongue and neck so greatly swollen, that, as he appeared to be in danger of asphyxiation, my partner sent him to St. Bartholomew's Hospital, where he was admitted and kept under observation for several days.

I was called to his house on September 6th, and found him in bed with greatly swollen face, neck, tongue and lips. The lower lip was fully one and a half inches thick, and the features almost unrecognizable. Previous treatment having proved futile, and, influenced by a consideration of its antitoxic and thrombin-producing properties, I decided to try hypodermic injections of normal horse serum. I gave 5 c.cm. that evening, and at intervals of forty-eight hours 5 c.cm. and 10 c.cm. The swelling subsided rather more slowly than usual, and the patient was about at the week end and went to the seaside on Sunday. There he developed a profuse erythematous rash covering the body and limbs, and came home three days later. The rash soon disappeared, except over the sites of inoculation on the arms, where it became eczematous and persisted for several weeks.

This patient remained under my care for nine weeks, during which time he had one slight recurrence of the oedema, involving the eyelids and subocular tissue. Up to the present he has had no further attacks and remains quite well. In view of the fact that prior to receiving the horse serum injections he had seven severe attacks occurring at almost regular weekly intervals, I think I can fairly claim that this treatment has proved definitely curative in the case described.—I am, etc.,

London, E.C., Dec. 19th, 1920.

W. A. M. SWAN.

Universities and Colleges.

UNIVERSITY OF LONDON.

THE title of professor of pharmacology has been conferred upon Dr. F. Ransom (London School of Medicine for Women).

Mr. F. F. Burghard, C.B., has been appointed the representative on the Senate of the Royal College of Surgeons of England for the remainder of the period 1919-23, in succession to Sir Charles Ballance, K.C.M.G., C.B., M.V.O., resigned.

The first lecture arranged under a scheme for the exchange of lecturers in medicine between England and Holland will be given at the rooms of the Royal Society of Medicine (1, Wimpole Street, W.1) by Dr. J. K. A. Wertheim Salomonson (Professor of Neurology in the University of Amsterdam) on "Some Considerations on Tonus and Reflexes" at 5 p.m. on Monday, January 17th. The chair will be taken by the Vice-Chancellor of the University, Dr. S. Russell Wells. Five other Dutch lecturers will also give one lecture each, particulars of which will be announced later. The lectures, which will be delivered in English, are addressed to advanced students of the University and to others interested in the subject. Admission is free, without ticket.

A course of eight lectures on the Physiology of the Embryo, Foetus, and Newly-born will be given by Professor M. S. Pembrey, M.D., in the Physiological Theatre, Guy's Hospital, at 4.30 p.m. on Thursdays, January 13th, 20th, 27th, February 3rd, 10th, 17th, 24th, and March 3rd. The lectures are addressed to advanced students of the University and to others interested in the subject. Admission is free, without ticket. [The course of lectures arranged to be given by Mr. J. A. Gardner has been postponed.]

Applications for the post of Professor of Obstetrics and Gynaecology and Director of the Obstetrical and Gynaecological Unit at the London (Royal Free Hospital) School of Medicine for Women (salary £2,000 a year) must be received by the Academic Registrar at the University by January 15th.

Applications for the Graham scholarship in pathology, value £400 per annum for two years, founded by the will of the late Dr. Charles Graham to enable a "young man to continue his pathological researches, and at the same time to secure his services to the School of Advanced Medical Studies connected

with University College Hospital as a teacher under the Professor of Pathology," must be received by the Principal Officer at the University by January 17th, 1921.

UNIVERSITY OF ST. ANDREWS.

At a meeting of the University Court on December 18th, the Very Reverend Principal Galloway, who presided, congratulated Professor Irvine on his appointment as Principal of the University.

Mr. D. M. Grieg's resignation of the post of lecturer in clinical surgery was accepted, and an expression of recognition of his services as a surgeon was adopted.

The following appointments were made: *Lecturers in Clinical Surgery*, Mr. John Anderson, D.S.O., and Mr. W. L. Robertson, M.C.; *Clinical Surgical Tutors*, Mr. John Taylor and Mr. F. A. Brown; *Clinical Tutor in Gynaecology*, Miss Margaret Fairlie; *Lecturer in Pathology*, Mr. G. R. Tudhope; *Honorary Demonstrator in the Department of Anatomy*, Miss Edith D. Dobbie; *Assistant to the Professor of Surgery*, Mr. F. A. Brown.

The following candidates have been approved at the examinations indicated:

THIRD M.B., Ch.B. (*Forensic Medicine and Public Health*).—D. A. K. Cassells, G. R. M. Cordner, W. A. Steel.
FINAL M.B., Ch.B.—Margaret J. M. Cuthbert, Jean H. D. Fleming, Mabel Hodgson, Frances L. Kuiper, Margherita M. Liller, Christian E. Little, J. B. Macdonald.

LONDON SCHOOL OF TROPICAL MEDICINE.

THE following candidates have passed the examination of this school at the termination of the sixty-fourth session, October-December, 1920:

* P. A. Buxton ("Duncan Medal"), * Surgeon Lieut.-Commander H. R. Parker, R.N., * H. G. Wiltshire, * L. C. D. Hermite, * Major W. B. Cullen, I.M.S., * Captain C. Heppenstall, I.M.S., * R. H. Liscombe, * Captain R. E. Flowerdew, I.M.S., S. C. Boso, E. R. Kellersberger, G. V. Allen, A. A. Donham, Captain H. S. Haji, I.M.S., A. S. Paranjpe, A. D. Gupta, C. J. Caddick, Z. Khaled, P. T. Liang, A. H. Patel, W. R. Taylor, D. F. Maya, S. Somasundram, W. E. de Silva, F. V. Jacques, Miss E. B. Salter, A. M. Kirdany, A. W. Hooker, Miss E. Lombard, A. K. Moilliet, Miss M. Gore, A. R. Mehta, O. van Stenis, Miss A. Gore, J. M. McCleery, Miss D. G. D'Abreu, A. F. Abbassi, E. S. Palmer, K. Ponniah, L. M. S. Parmanand, A. S. Westmorland, E. T. Saravanamuttu.

* With distinction.

Obituary.

THOMAS H. LIVINGSTONE, M.D., F.R.C.S. EDIN.,
Newcastle-on-Tyne.

THE death occurred on Christmas morning, at 38, Jesmond Road, Newcastle-on-Tyne, of Dr. Thomas Hillhouse Livingstone. He was the second son of the late Dr. Thomas Livingstone of Stanhope in Weardale, who was for over thirty years in practice at Stanhope, and who occupied a very prominent position in the public and social life of the dale. Dr. T. H. Livingstone was educated at Wolsingham Grammar School and Uppingham. He then proceeded to Edinburgh University, where he graduated M.B., Ch.B. in 1899. He filled the post of house-surgeon at Rochdale Infirmary, and later carried on his father's practice at Stanhope with much acceptance till 1903. He then returned to Edinburgh for a period, and took the M.D. degree and F.R.C.S. Edin. diploma, afterwards settling in practice in Newcastle. He became an honorary surgeon to the Hospital for Sick Children, and retired from this position in 1912. He was then appointed surgeon to the Throat, Nose, and Ear Hospital, Newcastle. During later years he confined his work entirely to this special branch, to which he had always had a leaning, and in it he had the satisfaction of being able to do much good work. He held a commission in the Territorial Force, and was mobilized at the outbreak of the war. He was under orders to proceed to France when he became seriously ill, and was admitted to the 1st Northern General Hospital with the malady which eventually proved fatal. Partially recovering from this illness, he was attached to the ear and throat department of the 1st Northern General Hospital. In 1914 he was made a vice-president of the Ear, Nose, and Throat Section at the annual meeting of the British Medical Association at Aberdeen. By nature he was of a most refined and gentle disposition, a gentleman in the truest sense of the word. He was possessed in a marked degree of that innate courtesy and kindness to others which one likes to associate with the profession. He was greatly attached to his native dale, and occasional visits from Newcastle to his old home in the country always gave him the utmost pleasure. To his many friends both in Weardale and Newcastle his death at the early age of 43 has come as a great grief. His remains were interred in the old churchyard of Stanhope.

The Serbires.

TERRITORIAL DECORATION.

THE King has conferred the Territorial Decoration upon the following medical officers of the Territorial Force:

Lieutenant Colonels A. W. Macintosh, 1st Scottish General Hospital, and (Brevet Colonel) Alexander Napier, V.D. Honorary Surgeon Colonel (Honorary Surgeon Colonel ret'd. Vols.) 4th Scottish General

lion, Gordon Highlanders, ding Divisional Engineers, d Ambulance J. W. Macbride Field Ambulance, rbert Hospital, Woolwich, al Scots id Home Counties Brigade,

R.F.A. (ret.)

DEATHS IN THE SERVICES.

Lieut. Colonel Richard Henderson Castor, Madras Medical Service (ret.), died of pneumonia at Croydon on December 30th, 1920, aged 59. He was born on May 12th, 1861, the son of Captain John Castor, master mariner, of Cochin, took the M.R.C.S. and L.R.C.P. Lond. in 1884, and entered the I.M.S. as surgeon on September 30th, 1886. He served in the Burmah campaigns of 1887-89, receiving the frontier medal with a clasp, and in May, 1890, went into civil employ in Burmah, in which province he spent the remainder of his service (thirty years). He became lieutenant colonel on September 30th, 1906, received extension of service for four years during the war, and retired on November 9th, 1920, only six weeks before his death. He received the Kaiser i Hind medal (1st class) on June 3rd, 1919.

Medical News.

THE Earl of Radnor has accepted the office of President of the Thirty second Congress of the Royal Sanitary Institute, to be held at Folkestone from June 20th to 25th, 1921.

SIR JAMES KINGSTON FOWLER will deliver an address entitled "The Colonial Medical Service" at the Middlesex Hospital Medical School on Thursday, January 20th, at 3 p.m., when the Earl of Athlone will preside.

THE Medical Branch of the Board of Education has been transferred from Cleveland House, St. James's Square, S.W.1, to Budgevater House, Cleveland Square, S.W.1 (telephone 3410 Gerrard).

WE have received from Dr. Ernest W. Jones, the Honorary Secretary, a copy of the programme of the newly formed Birmingham Medico-Psychological Society. The President is Lieut.-Colonel A. W. Moore. Meetings for the discussion of papers are held monthly on Wednesday afternoons.

DR. OLIVER K. WILLIAMSON, physician to the City of London Hospital for Diseases of the Chest, has been appointed Professor of Medicine in the Medical School of the University College, Johannesburg.

A PROPOSAL has been made to install new x ray apparatus and equipment at the Bolingbroke Hospital, Wandsworth, as a memorial to the late Dr. Cecil Lister, whose early experiments with x rays were carried out in that institution.

CAPTAIN W. L. ELLIOT, M.P., Dr. A. Mearns Fraser, Dr. Jane Loumei Hawthorne, Surgeon Vice Admiral Sir James Porter, K.C.B., K.C.V.G., and Mr. A. H. Tubby, C.B., C.V.G., F.R.C.S., have recently joined the Executive Committee of the Society for the Prevention of Venereal Disease.

AT the meeting of the Medico Legal Society to be held at 11, Chandos Street, W.1, on Tuesday, January 18th, at 8.30 p.m., Dr. H. Gibson Sutherland will read a paper on "Medical evidence in the Stanton murder trial."

A SPECIAL general meeting of the West London Medico-Chemical Society will take place in the society's rooms at the West London Hospital on Friday, January 14th, at 8.30 p.m., in order to discuss the Medical Consultative Council's interim report on the future provision of medical and allied services. Medical practitioners are cordially invited to attend and take part in the discussion.

COURSES of lectures on infant care, to be held in London and at Worcester, have been arranged by the National Association for the Prevention of Infant Mortality and for the Welfare of Infancy; an elementary course in London has been arranged by the association in conjunction with the National Society of Day Nurseries. Particulars may be obtained from Mrs. Halford, Secretary of the National Association for the Prevention of Infant Mortality, 4 and 5, Lavender Square, London, W.C.1.

IN the Psychological Department, University of London, King's College, Strand, W.C.2, Dr. William Brown will give a course of ten lectures on psychopathology on Tuesdays, at 5.30 p.m., during the Lent term, commencing on Tuesday, January 18th. These lectures are open to medical students and medical practitioners without fee or ticket.

Letters, Notes, and Answers.

As, owing to printing difficulties, the JOURNAL must be sent to press earlier than hitherto, it is essential that communications intended for the current issue should be received by the first post on Tuesday, and lengthy documents on Monday.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the BRITISH MEDICAL JOURNAL alone unless the contrary be stated.

CORRESPONDENTS who wish notice to be taken of their communications should authenticate them with their names—of course not necessarily for publication.

AUTHORS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate with the Office, 429, Strand, W.C.2, on receipt of proof.

In order to avoid delay, it is particularly requested that ALL letters on the editorial business of the JOURNAL be addressed to the Editor at the Office of the JOURNAL.

THE postal address of the BRITISH MEDICAL ASSOCIATION and BRITISH MEDICAL JOURNAL is 429, Strand, London, W.C.2. The telegraphic addresses are—

1. EDITOR of the BRITISH MEDICAL JOURNAL, *Antiochy*,

MANAGER
telephone.

2630 Gerrard
MEDICAL SECRETARY *Mediscera, Westrand, London;*
address of the Irish Office of the
6, South Frederick Street, Dublin
telephone 4737, (Dublin), and of
Square Edinburgh (telegrams
e. 4561, Central).

QUERIES AND ANSWERS.

INCOME TAX.

"PUZZLED" asks "Should dividends from war loan, which are income tax free, be included as assessable income or not?"

* Our correspondent presumably refers to the tax compounded 4 per cent war loan issue. Interest thereon should not be "returned for assessment" on page 2 of the ordinary form of declaration, but should be included in any statement of total income at the gross equivalent of the net amount received—that is, at £r plus three sevenths of £r. It will not be assessed to income tax if its precise nature is shown, and is not exempt from super tax.

"R.P.R." has been applied to for payment of income tax assessed on him for the year 1915. Can he now claim to have the assessment adjusted?

* The legal position is that the claim should have been made by April 5th, 1917, but we anticipate that objection would not be raised by the authorities to the claim being put forward now in view of our correspondent's absence on military service and of his statement of the actual income of the year made through Holt's Agency, which might reasonably be regarded as an intimation of claim. We suggest that he might write in this sense to the local inspector of taxes. As regards the annuity, a claim can be put in by the recipient on or before April 5th, 1921, in respect of the three years ending April 5th, 1920, but not as regards earlier periods.

LETTERS, NOTES, ETC.

ARTIFICIAL LIMBS.

CAPTAIN H. H. C. BAIRD, D.S.O., in the course of a letter which we have not space to print in full, writes:

Whilst welcoming your leading article on artificial limbs as a means of keeping this vital problem before the public eye, I regret that you should have thought it either desirable or necessary to have introduced the personal factor in your reply. To say that we, who are interesting ourselves in the welfare of the limbless, are the dissatisfied, is absurd if for no other reason than that we happen to be the highly satisfied who have tasted the joys of wearing an artificial limb without having, and our only desire is that the same joys may be brought within the reach of each and all of the thousands of others who have suffered a similar affliction. Then, again, you represent that we hold a brief for one particular male of limb as if we had some axe to grind. This is not only absurd, but a most unfortunate misrepresentation of our case. What we have asked for is an impartial committee, on which

limbless men themselves shall have a fair and reasonable representation, which shall investigate every phase of the problem of artificial limb supply. Also, as a further proof of our impartiality, it may interest you to know that we, the "mouthpieces of the dissatisfied," as you term us, are now, at the request of the Ministry of Pensions, putting their standardized light metal model to practical tests. But this impartiality on our side also looks for justice—or is it favour?—to all makers of artificial limbs, whether they belong to the British Association of Limb Makers or not. On this account we should expect the impartial committee, when set up, to investigate all that has passed between Messrs. Desoutter Brothers and the Ministry of Pensions during the last two years, and exactly how far Mr. Desoutter himself, the pioneer of light metal legs, with which type all other makers are now experimenting, has been consulted in the development of the Government model. Such an investigation would throw a little light on to such matters as cost, methods, and delay; and exactly to what extent the interests of the wearers of artificial limbs, to say nothing of the taxpayers, have been studied in the past and how these can best be studied in the future. Presumably also this committee would investigate the results of the practical tests of light artificial legs carried out by the British Red Cross many months ago, which up to the present have never yet seen the light of day. In regard to the other points raised in your article relating to curvature of the spine and weight, etc., I do not propose to deal with these in detail. Obviously the only way of arriving at a true solution of this problem is not through the medium of leading articles or letters in the press, but by a thorough and unbiased investigation of the practical experiences of wearers of artificial limbs themselves, such as we have asked for. No doubt you have concrete evidence in support of your statement that "it is certain that a very large number, and probably the great majority, of pensioners are well satisfied with the limbs supplied by the Ministry of Pensions, but they do not feel called upon to write to the daily papers and say so." All I ask is that your evidence may be placed alongside ours, together with that of any others whose evidence may be called. It will then be left to that committee, not to you nor to us, nor the limb-makers, nor the surgeons, nor the Ministry of Pensions, to decide in co-operation with limbless men themselves whether the present state of affairs is satisfactory or not; and whether it has been "disgruntlement" or "right" which has caused us to raise our voice.

TRIPLETS.

DR. H. WESSEN HUSBANDS (Taunton) writes: The following cases, which occurred in my practice last year, may possibly be of some interest to certain members of the profession from a statistical point of view. According to the authorities, triplets occur in about 1 in 7,000 to 10,000 labours; the children are generally small, poorly developed, and often do not survive their birth many days. In March I was called by the district nurse to Mrs. S., aged 27, first pregnancy. She was delivered of two girls and a boy.

Weight of first girl	6 lb.
" of second girl	6½ lb.
" of boy	3½ lb.

All are alive and doing well. In October I was called to Mrs. T., aged 37, seventh pregnancy. She was delivered of three boys.

Weight of first	8 lb.
" of second	7½ lb.
" of third	7 lb.

All are alive and doing well. Unfortunately in the last case the mother developed puerperal insanity at the end of the second week, and was removed to the asylum, where she died three weeks later. It certainly must be a rarity for one medical practitioner to have two cases of triplets in six months.

EMETINE IN BILHARZIASIS.

IN our issue of October 30th, 1920, Dr. Andrew Balfour, in response to an inquiry by Dr. Esser, of Rustenburg, Transvaal, gave a list of references to papers describing the use of emetine in bilharziasis. Dr. Balfour pointed out that the drug had been given a considerable trial, but questioned whether the evidence yet adduced warranted its substitution for antimony. He referred, among other writers, to Dr. Diamantis of Cairo, from whom we have received a letter dated December 4th, 1920. In the course of it he says that he was the first to employ a radical treatment of bilharziasis, by recommending emetine hydrochloride, by pointing out the indications for its use, and by stating the suitable dose. The value of the treatment has, he says, been proved, and the results are not to be despised; it is being used by many Egyptian practitioners every day. "There remains, however," Dr. Diamantis continues, "the question of the toxicity of emetine given intravenously. Is it really worth while, in of emetine given intravenously, to run the risk of producing the toxic effects of emetine given intravenously?" In my earlier publications I stated clearly the indications for adopting this treatment, the dose which should be used, and accidents to be feared and the means of preventing them, and gave a detailed description of the technique. I have injected into the vein of an adult in one dose 0.12 gram of emetine; I have never had any untoward effects. . . . The

method of administration is within the competence of any practitioner who knows how to give an intravenous injection. I employ the ampoules of emetine as supplied by Clin, Burroughs Wellcome, or Parke Davis, without the addition of saline solution. It is not necessary to take the patients into hospital. My experience has satisfied me that ten to twelve injections, at intervals of three to five days, will suffice for the radical cure of the adult, the amount of emetine given being from 0.85 to 1.05." In reply to Dr. Esser, Dr. Diamantis states that he has had no experience of the intravenous injection of emetine in amoebic dysentery; bilharzial haematuria, he points out, is only a local affection, the general condition of the patient being satisfactory, whereas dysentery, being a general disease, the patient is in a bad condition, and the myoc the poison of dysentery, is not by emetine in addition. A great of bilharzia is, Dr. Diamantis considers, that it can be given by hypodermic injection as stated in a communication made by him to the Institut Egyptien in 1916. Dr. Diamantis goes on to note—what he considers the remarkable fact—that tartar emetic has an effect not only in bilharziasis, but also in kala-azar, which is a leishmaniasis, and that emetine acts not only in bilharziasis, but also, as observed by Dr. Photinos of Athens, when injected locally in oriental sore, which again is a leishmaniasis.

DR. ESSER writes from Rustenburg, Transvaal, under date November 26th, 1920, to thank Dr. Balfour for his reply. Intramuscular injection, while a much simpler procedure than intravenous, must, Dr. Esser points out, be done with strict aseptic precautions to avoid the risk of abscess, and as emetine is poisonous and has a cumulative action, it is important not to give more than is absolutely necessary to cure. The advantages of the intravenous route are, in Dr. Esser's view: (1) That the pain, swelling, and discomfort, which often follow subcutaneous or intramuscular injection of emetine, are absent or very slight; (2) a smaller quantity of the drug will be needed. He thinks that the intravenous, being the more direct route, will prove the more effective and certain method of cure. Facilities can hardly, he says, anywhere be lacking for making a little normal saline solution, boiling it, and dissolving in it one or more tablets of emetine. At the same time he suggests the use of the sealed glass tubes (such as the ampoules mentioned by Dr. Diamantis).

ONE WAY OF SELECTING A HEALTH RESORT.

DR. JOHNSON SMYTH (Bournemouth) sends us the following note: A patient, 60 years of age, informed me he had decided on permanently residing in Bournemouth. He gave as his reason that since retirement he has spent considerable time in visiting the graveyards from Deal to Land's End, and he made the remarkable discovery that he found on the tombstone records a far higher percentage of persons dying at 81 and over in Bournemouth than elsewhere. "That's good enough for me" was his final remark.

CORRECTION.

DR. G. C. GARRATT'S letter last week (p. 31, col. 1) contains two errors which were uncorrected because time did not allow us to send him a proof. The word "discussion" in line 14 should be "dissension" and "War Pensions Committees" should be substituted for "county councils" in the 12th and 13th lines from the foot of the column.

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 33, 34, 36, 37, 38, and 39 of our advertisement columns, and advertisements as to partnerships, assistantships, and locum tenencies at pages 35 and 36.

THE following appointments of certifying factory surgeons are vacant: Dalmellington (Ayr), Fishguard (Pembroke).

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Six lines and under	0 9 0
Each additional line	0 1 5
Whole single column (three columns to page)	7 10 0
Half single column	3 15 0
Half page	10 0 0
Whole page	20 0 0

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Tuesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive post-restante letters addressed either in initials or numbers.

MEDICINE.

37 Transient Acute Poliomyelitis in the Adult

CICCARELLI (*La medicina pratica*, August 31st, 1920) records a case of transient acute poliomyelitis following influenzal bronchopneumonia in an adult, and characterized by complete loss of power in the lower limbs, abolition of the knee jerks, absence of sensory changes, integrity of the sphincters, and wasting of muscles. A diagnosis of acute poliomyelitis of the lumbosacral segment of the cord was made owing to the sudden onset, rapid development, and degenerative character of the paralysis. Gradual improvement took place, so that by the end of four months the patient could walk three kilometres with the aid of a stick.

38 Modern Methods of Treatment in Pulmonary Tuberculosis

VALLARDI (*Tuberculosis*, August, 1920) alludes to treatment by certain metals—for example, copper, gold, nickel, cobalt—which *in vitro* have been shown to have a marked predilection for tubercle bacilli. For the present this line of treatment is on its trial. Next he discusses the efforts to produce active immunization by tuberculin preparations, etc. It is better to begin with specific treatment by tuberculin; after the maximum degree of resistance to the poisons of the tubercle bacillus has been determined, one may continue with bacillary emulsions. The great difference in patients' reactions to tuberculin may be partially explained by remembering that tuberculin is a mixture of variable substances, and that each patient has an individuality which may change. Rapid forms of phthisis, or cases in which there is much congestion and tendency to frequent haemorrhage, are unsuitable for tuberculin treatment. Haemoptysis alone is not a contraindication. Attempts at passive immunization are repudiated by the various serums—for example, Maragliano's or Marmorek's. There is a danger in long continued serum treatment of the formation of anti-antitoxins, which assist in the development of the disease. Where tuberculin is contraindicated, the so called immune bodies introduced by Spengler in 1908 may be useful. Artificial pneumothorax is favourably spoken of as arresting the disease, stopping haemorrhage, and checking the spread of toxins into the lymphatics. Radiography shows that the apparent obliteration of cavities by this method is not as real as it seems. Pleural adhesions and bilateral tuberculosis are the chief contraindications; cases with heart disease, marked pulmonary emphysema, and enteroptosis are also unsuitable. Cases with localized ulceration, tendency to caseation and frequent haemoptysis are suitable. Enough gas should be introduced to obtain a weak positive pressure; usually four to six introductions are necessary to reach the 1,700 to 3,000 c cm. required. As a rule the pneumothorax should be maintained for two years.

39. Syphilis simulating Pulmonary Tuberculosis.

SØRENSEN (*Hospitaletidende*, September 1st, 1920) has seen in Java as many as seven cases of pulmonary syphilis simulating phthisis. A feature common to almost all these cases was the absence of physical signs over the apices of the lungs; elsewhere they seemed to be riddled with disease, and the clinical picture was typical of pulmonary tuberculosis in the last stage. The author was at first inclined to regard this pulmonary manifestation of syphilis as more or less peculiar to the tropics, but during a recent stay in Holland he observed a similar case in a woman suffering from "phthisis" and osteitis of the forehead. Under antisyphilitic treatment the pulmonary disease cleared up even more rapidly than the osteitis. In several of his cases the author could find no history of syphilis, although his patients were perfectly candid as to their past. There was also, in some cases, no other clinical evidence of syphilis than the chest signs. His evidence for regarding the pulmonary condition as syphilitic was a positive Wassermann reaction, absence of tubercle bacilli in the sputum, and amazingly rapid improvement, and in some cases complete recovery, after the institution of antisyphilitic treatment. The author also recalls two cases of persistent fever simulating typhoid fever in which the intramuscular injection of mercury reduced the temperature to normal within two days.

40

A Case of Syphilitic Aortitis.

MARCIALLIS (*Riv. Osped.*, August 31st, 1920) remarks that when a cardiac affection has reached the final stage, it is often difficult to diagnose during life the exact nature and seat of the affection, the physical signs are confused, and the clinical picture is due to the final anatomical lesions and not to the pre-existing ones. Cardiac failure is not always the result of a valvular defect but may be due to any cause, even an extracardiac one, when the reserve energy of the heart is exhausted. Marciallis records the case of a man, aged 42, who on admission to hospital showed typical signs of cardiac failure, including cyanosis, dyspnoea, hydrothorax, and oedema of the lower limbs. He had contracted syphilis at the age of 20, and four months previously had had an attack of transient hemiplegia. The Wassermann reaction was positive. Considerable relief followed thoracentesis, but death took place suddenly the following day. The autopsy showed large raised fibrous patches at the origin of the aorta, one of the patches completely occluding the origin of the left coronary artery. The left ventricle was dilated and the right hypertrophied.

41

Prognosis in Syphilis

MOXFRINI (*Rev. med. Suisse rom.*, September, 1920) maintains that it is impossible to form a sound prognosis in the treatment of syphilis without making an examination of the cerebro spinal fluid, in old cases of syphilis, especially when the nervous system is affected, the Wassermann reaction may be negative in the blood when it is positive in the cerebro spinal fluid. He records a case in a man, aged 40, who, in spite of vigorous treatment and a negative Wassermann reaction in the blood, eighteen months after the onset of syphilis and five weeks after the last injection of "606," suddenly developed symptoms of meningo-encephalitis which might have been prevented had a lumbar puncture been made when the blood was examined for the Wassermann reaction.

42.

Parathyroid Tetany in Infancy.

CLARK (*Glasgow Med. Journ.*, October, 1920) describes two instances, occurring in infants, of what he regards as parathyroid tetany, similar to that which develops in animals after the removal of these glands. The patients were aged 15 months and 2½ years respectively. The outstanding symptoms were idiocy, with depression and apathy, fibrillary twitchings in the muscles, a staring appearance of the eyes, jerking movements of the limbs, inability to balance, a tendency passively to preserve unusual positions in which the subjects had been placed, and frequent convulsions. Treatment with dried parathyroid gland substance (one tenth of a grain thrice daily) caused immediate improvement, one child appeared to be completely cured and the other gradually improved. In one case the gland substance was discontinued twice, and on both occasions the child was not so well, but recovered as the administration was resumed. In neither case was there impairment of nutrition, carpopedal spasm or Trousseau and Chvostek phenomena were not observed.

43.

Acrobrachycephaly.

PARK and POWERS (*Amer. Journ. of Diseases of Children*, October, 1920) print abstracts of the history of 24 cases, and add the record of a personal case of so called "acrocephalosyndactylism," or acrobrachycephaly—a disease characterized by unusual configuration of the cranium, together with malformations of the extremities. They also report two cases of scaphocephaly, with malformations of the extremities. Of the 25 subjects of the first named deformity, 11 were less than 18 months old, and 6 were newborn infants; the oldest was 24 years. The most important characteristics of acrobrachycephaly are as follows: The head is abnormally high, short, and broad, its vertical diameter being greatly increased by an abnormal extension upwards of the cranial vault, and the occiput being flattened so that in some cases the back of the head is flush with the neck, and the surfaces of the face and of the back of the head are almost parallel. The angular process of the frontal bone, and the zygomatic arches are unusually prominent, and the forehead is of abnormal height and breadth. The palpebral apertures are set obliquely, so that their transverse axes are inclined outwards and slightly downwards. The eyes are prominent, sometimes to a very pronounced extent, so that in one

case manual replacement of a dislocated right eyeball was necessary on eleven occasions. The facies is that of chronic nasal obstruction, and almost invariably there is a narrow and high palate; in five cases the hard palate was partially cleft, and in six the uvula was bifid. The deformities of the hands range from complete syndactylism, in which the fused fingers, thumb, and body of the hand form a spoon-shaped mass, concave on the palmar surface, to minor conditions of partial syndactylism or other deformities affecting one or two digits. The toes show similar appearances, and hallux varus is invariably present. In certain cases there is limitation of movement at the elbows, shoulders, or wrists. The intelligence may be normal or subnormal, and walking as a rule is begun about the eighteenth month. Syphilis appears to play no part in the etiology. The authors are inclined to believe that the malformation of the skull is in existence, in a potential sense at least, in the blastemal cranium.

44. Senecio Poisoning.

WILLMOT and ROBERTSON (*South African Med. Record*, September 25th, 1920) record preliminary investigations of "senecio disease," prevalent in the George and Mossel Bay districts of the Cape Province. The malady begins with slight symptoms of digestive derangement, followed by abdominal pain, diarrhoea, haematemesis, melæna, enlargement of the liver, and ascites; acute as well as chronic forms are found. Albertyn suggested, in 1918, that the disease was of dietetic origin, and samples of meal and white bread which had been eaten by persons affected were found to be contaminated with the seeds and other portions of the plants *Senecio ilicifolius* and *Senecio burchellii*. Willmot and Robertson found that in acute cases the liver was enlarged, with rounded edges, and raised, engorged areas, the size of a hazel nut or walnut, projecting on the surface. More advanced cases showed round-celled infiltration and hepatic cirrhosis. Guinea-pigs and white rats fed on infected meal or on the dried flower heads and seeds of senecio became emaciated, and many died: the *post-mortem* findings were exactly similar to those made in human subjects.

45. Disturbance of Deglutition in Aortic Disease

ACCORDING to NICOTRA (*Il Policlinico*, Sez. Prat., August 30th, 1920), x-ray examination shows that the disturbances of deglutition in aortic disease are not due to the mechanical action of pressure on the oesophagus, but are caused by a motor neurosis secondary to degeneration of the nerve fibres of the oesophagus and pharynx. In all such cases antisyphilitic treatment is indicated.

SURGERY.

46. Coma after Injury of Frontal Lobes.

MILLAN (*Paris méd.*, October 2nd, 1920) records the case of a girl, aged 20, who shot herself in the head, the bullet passing through the anterior part of the frontal lobes. The Rolandic area was not affected, as there was no hemiplegia or monoplegia. In addition to left facial paralysis and right internal squint due to fracture of the petrous portion of the temporal bone, the patient presented a comatose state, the remarkable feature of which was its close resemblance to ordinary sleep. There appeared to be a pure and simple suspension of the intellectual faculties. There was no stertor, Cheyne-Stokes breathing, or other respiratory anomaly. Respiration though weak was regular and not hurried, and the pulse, though small, was also regular and not rapid. Although there was incontinence of urine, sensibility remained almost normal, as was shown by defensive movements on the application of painful stimuli, just as in ordinary sleep. The corneal reflex was present on both sides. The temperature never rose above 101.8° F. Apart from a slight squint complete recovery took place.

47. Treatment of Osteomyelitis with Antistaphylococcal Vaccine.

BOUVIER (*Gaz. hebdomadaire des Sci. méd. de Bordeaux*, October 10th, 1920) records a case of osteomyelitis of the left tibia in a man who was operated on first at the age of 35 and later at 50. Since on the second occasion the wound was very slow in healing and pustules containing staphylococci appeared in the neighbourhood of the wound, a subcutaneous injection of Le Moignic's antistaphylococcal lipovaccine was given. Complete recovery took place within two and a half months, as compared with seven months after the first operation.

48. Medical Treatment of Incipient Cataract.

SCALINCI (*Rif. Med.*, September 18th, 1920) pleads for a more extended use of medical treatment in early cataract. He assumes that the disease is in some way related to nutrition; any discoverable cause should be treated, but in addition benefit can be derived from the use of iodides, internally and locally. Inasmuch as iodine can be recognized in the aqueous humour very shortly after oral administration, there is perhaps not much extra benefit to be derived from local administration, whether by ointment, local baths, cataphoresis or subconjunctival injection (the author prefers sodium iodide with the addition of a small quantity of calcium phosphate). Obviously not every cataract, nor any cataract at an advanced stage, is susceptible of benefit from the iodide treatment, and the decision must be left to the ophthalmic surgeon. Dor says that he can arrest 8 out of 10 cases of cataract by this treatment, thus avoiding operation. The treatment should be continuous for at least three to six months.

49. Treatment of Furuncle of the Lip.

LANZ (*Nederl. Tijdschr. v. Geneesk.*, December 4th, 1920) emphasizes the danger of incising a furuncle of the lip by relating how two of Kocher's assistants at Berne died of pyæmia due to this cause. He urges that furuncle of the lip should be treated from the first as a serious disease. The patient should be put to bed and prevented from scratching or pressing his lip. Conservative treatment should be adopted in the form of poultices or dressings of 1 in 1,000 salicylic acid. Instead of an incision the necrotic centre of the pustule should be punctured with a thermo-cautery, or preferably a galvano-cautery. While the knife opens up the blood and lymph channels the thermo-cautery closes them, and thus diminishes the danger of infection of the blood stream.

50. Mastitis in Malta Fever.

BENEDETTI (*La Clinica Chirurgica*, March-April, 1920) records a hitherto undescribed complication of Malta fever. The patient was a woman, aged 52, who developed a chronic suppurative mastitis of the left breast in convalescence from Malta fever of three months' duration. Histologically the inflammatory infiltration was constituted by leucocytes which were almost exclusively of the mononuclear type. This mononucleosis in the inflammatory processes of Malta fever is due to the morphology of the blood in that disease, and serves to distinguish it from the inflammatory processes due to ordinary pyogenic organisms. Mononucleosis in infectious diseases is rare, the only other diseases in which it is found being chronic malaria, kala-azar, and the second stage of typhoid fever.

51. Intestinal Perforation in Typhoid in Childhood.

GIOSEFFI (*Rif. Med.*, October 16th, 1920), in view of the rarity of such accidents in childhood, reports the case of a girl, aged 14 years, who on the tenth day of an attack of typhoid fever was seized with sudden pain in the right lower abdomen. On the following day, as there were signs of rigidity on the right side of the abdomen and the general condition was worse, perforation with subsequent peritonitis was suspected, and laparotomy performed. On opening the abdomen pus and gas escaped, and there was evidence of recent peritonitis with adhesions and flakes of lymph. The peritoneum was washed with physiological solution and a drain inserted. Widal's test was positive at this date, and Eberth's bacillus grew in blood culture. The child made an excellent recovery.

52. Simple Perforating Ulcers of the Caecum and Colon.

CHARBONNEL (*Gaz. hebdomadaire des Sci. méd. de Bordeaux*, October 10th, 1920) records a personal case, and has collected 5 others from the literature, of simple ulcers of the caecum or colon, for which no local or general cause—such as dysentery, tuberculosis, or actinomycosis—could be found. Charbonnel attributes their occurrence partly to infection from faecal stasis and partly to circulatory disturbances in the caecum. The ulcer has a punched-out appearance, with its margins slightly, if at all, indurated. It is usually single, but is sometimes accompanied by one to three smaller perforations situated on the anterior surface of the caecum and colon. The appendix is always healthy. Histological examination shows ordinary inflammatory changes and vascular lesions consisting in haemorrhagic infiltration.

53 Congenital Occlusion of the Small Intestine.

ROCHET and WERTHEIMER (*Lyon Chir.*, September October, 1920) record three cases in this condition, two of which were found in infants who died five and fifteen days respectively after birth, and one in an anencephalous foetus who presented numerous congenital malformations. Congenital malformations of the intestine may vary in number and position. They may be multiple, but are as often single, as in two of the writers' cases, and occur most frequently in the duodenum, jejunum, and upper part of the ileum. The part of the alimentary canal below the lesion shows atrophy and arrest of development, although occupying a normal position, so that in a full term child the size and calibre of the intestine are those of a four months foetus.

54 Torticollis

AIEVOLI (*Riv. Med.*, October 16th, 1920), in a review of recent knowledge concerning wry neck, points out the difficulty of determining the exact cause. Although it is usually classified as congenital or acquired, it is doubtful how many of the so called congenital group are really congenital (out of 95 cases in a Milan hospital 78 were classified as congenital). Some of these congenital cases are perhaps due to obstetric injuries. Females are more often affected than males, and more often on the right side, males slightly more often on the left side. The torticollis may be sternal, clavicular, or total, according to the parts of the sterno cleido mastoid chiefly affected. The pure clavicular type is often associated with abnormal history, the types associated with cranio facial deformity or with spinal curvature must be considered separately. For treatment open operation is generally practised, but in some cases where a small scar is desired, a subcutaneous tenotomy may be sufficient. After operation some form of extension and counter extension is necessary.

55. Dead Grafts for Tendon Repair.

DURAND (*Lyon Med.*, October 25th, 1920) in three cases has restored the continuity of the divided tendons of the digital flexors or extensors by using dead grafts taken, according to Nagotte's method, from tendons of embryos. Directly after slaughter of the cow the tendon is removed, with aseptic precautions, from the foetus, and preserved for eight to ten days in 90 per cent. alcohol, and afterwards in 60 per cent alcohol. The graft may be kept sealed in this medium for several months. After operation the member is immobilized for ten days in a position which will relax the tendon concerned. In Durand's three cases the presence of the graft was well borne, but in one no restoration of function followed.

56. Cerebral Hydatid Cyst.

CARDENAL and CASTELA (*Rev. Españ. de Med y Cir.*, September, 1920) record the case of a boy aged 14 who suffered from epileptic attacks which had progressively increased in frequency from the time of a fall which occurred a year previously. This fall had caused a wound of the right parietal region and two hours' loss of consciousness, and had been succeeded by six weeks' pyrexia. Admitted to hospital, he was found to have right hemiparesis, with exaggerated reflexes, but no impairment of intelligence nor abnormalities of the fundus oculi. A flap of scalp and cranium was turned back in the left parietal region (the opposite side to that of the injury); opening of the dura exposed a cystic cavity (containing numerous daughter cysts) occupying more than one third of the left cerebral hemisphere. The daughter cysts and the internal lining membrane were removed and a gauze drain was inserted. The fist disappeared from the sixth day after operation. Subsequently, with the exception of some rigidity of the arm, the hemiparesis disappeared.

57. Hydatid Cyst of the Renal Pedicle

ACCORDING to DEMOLIN (*Journ de Med et de Chir. Prat.*, October 10th, 1920), the kidney comes next to the liver and lung in the order of organs liable to become the site of hydatid cysts. Of 2,111 hydatid cysts reported by Houzel, 115 occurred in the kidney. The diagnosis of the hydatid nature of the cyst is very difficult as long as it remains closed. Outbreaks of urticaria may arouse a suspicion, which is confirmed by laboratory examinations, especially eosinophilia in the blood and urine. When once the cysts have burst into the renal pelvis, the association of pain with an urticarial eruption, and the thick blood stained urine containing hydatid cysts reveal the nature of the

case. Exploratory puncture, which is an excellent method in cysts of the liver, is dangerous in the case of the kidney; for treatment, nephrotomy by the translumbar route, with drainage of the hydatid cavity, is the method of choice. In some cases nephrectomy combined with a dissociation of the renal pedicle may be required.

OBSTETRICS AND GYNAECOLOGY.**58 Incubation-Chamber Treatment of Premature or Very Small Infants**

HAUCH and RUGE (*Gynec. et Obstet.*, 1920, 11, 2) describe the treatment of newborn infants weighing less than 2,050 grams at the Righospitalet, in Copenhagen, where instead of portable "incubators" a large chamber is installed, in which the children remain continuously for some weeks, and in which nursing attendants and, if necessary, maternal feeding may be given. In nine years, among 13,425 births at the clinic, there were 521 instances in which the child weighed less than 2,050 grams, of these 521 infants, 145 were born dead, and 114 died within twenty four hours. Of four infants weighing less than 1,200 grams, three died; of 51 weighing 1,200 to 1,499 grams, 10 died; of 297 infants weighing 1,500 to 2,050 grams, 24 died. For all degrees of smallness of the infant, the percentage mortalities are much lower than those reported by Clédy, Henry, Budin, Porak Duante, or Lichtenstein. Hauch and Ruge attribute the low mortality at the Righospitalet to the use of large incubating apartments in preference to small portable incubating cradles. In common with other authors they recommend that washing of these newborn subjects should be deferred for from twenty four to forty eight hours, the body temperature is then found to be maintained at a much higher level than if the usual ablutions are performed shortly after birth. Another factor in the reduction of mortality in the clinic is careful isolation of babies showing signs of febrile catarrh, pneumonia, or pemphigus. As a rule the infants are fed with human milk; if this is impossible, with a mixture of cow's milk and barley water. Three hourly feeds during the day and a single feed during the night are recommended; if, however, the infant does not progress the intervals between the feeds are reduced to two hours. Collapse and cyanotic crises are treated by baths, artificial respiration, and hypodermic injections of 0.5 to 1 c cm. of camphorated oil, or of digalen. Two cases only have been encountered in which infants born before the twenty eighth week survived, both were born spontaneously of healthy mothers, and the respective weights were 1,150 grams and 1,250 grams. Only in 59 cases was it possible subsequently to trace the fate of these infants, of these 59 children, 71.2 per cent. were living at the end of one year. The average mortality rate in Copenhagen from 1907 to 1917, for all children born alive, was 10.6 per cent. during the first year.

59. An Operation for Complete Perineal Tear.

IMBERT (*Amer. Journ. of Surg.*, September, 1920) illustrates an operation which he has devised for complete tear of the perineum. A transverse incision is made, extending about 6 cm. on each side of the middle line, and separating the vulva from the anus. A flap of the mucous membrane is dissected from the vagina and removed; the vaginal and anal gaps are sutured edge to edge, and the rectal mucosa, if it has been torn, is sewn. The lozenge shaped gap which is left between the vulva and anus, in correspondence with the original transverse incision, is filled in by a lateral flap (whose attached base is anterior, and pointed free end posterior) taken from the skin and subcutaneous fat of the buttock.

60. Obstetrical Fracture of the Femur.

LE GRAND (*Gynec. et Obstet.*, 1920, 1, 6) describes a new method of continuous extension for obstetrical fracture of the femur. Continuous extension is applied to both thighs, which are maintained in a position of extreme abduction at the hip. A single padded splint is required, consisting of a rectangular piece of wood the length of which exceeds by a few inches the distance between the lower extremities of the two maximally abducted limbs. Traction is secured by placing beneath this splint an elastic band, the extremities of which are turned over at the end of the splint, where they are connected to the loops of strips of plaster, which (attached at one end to the outer side of the thigh) pass along the side of the limb, below the foot, and upwards again, to be fixed on the inner aspect of the thigh.

61. Vesico-uterine Fistula.

BRODHEAD (*Med. Record*, September 11th, 1920) records the case of a sixth normal spontaneous delivery lasting six hours, followed after three days by abdominal pain, fever, and disturbance of urination. Subsequently the patient became incontinent, and blood-stained urine was found escaping from the cervix; a large fistulous connexion was seen between the bladder and cervix. This closed within a few days. It is recorded that ten minutes before birth the patient received a hypodermic injection, probably of pituitary extract.

62. Pregnancy and the Thyroids.

ALBECK (*Gynec. et Obstet.*, ii, 1) interrogated 1,707 pregnant women, of whom 1,157, or 67.78 per cent., had suffered from severe vomiting. Of 358 who were able to furnish particulars of the interval which had elapsed between the commencement of the vomiting and the last menstrual period, the interval was eight days in 0.28 per cent., fourteen days in 12.8 per cent., three or four weeks in 36 per cent., six weeks in 10 per cent., eight weeks in 12.3 per cent., twelve to sixteen weeks in 9.2 per cent., and sixteen to twenty weeks in 0.5 per cent. Albeck believes that simple vomiting, intractable vomiting, and vomiting with jaundice and polyneuritis are all conditions of pregnancy toxæmia provoked by noxious substances proceeding from the embryo. He has found, from examination of the thyroid gland twenty-four hours after delivery in 1,581 women, that there is a constant relationship between the size and consistency of the thyroid gland and the intensity of the vomiting—women with a large soft thyroid rarely vomit during pregnancy; those with a small hard thyroid always vomit. Albeck compared also the histological appearances of the thyroid glands in gravid and non-gravid sows, the latter of which did not show any naked-eye enlargement of the gland. In the gravid sows minute examination showed constantly hyperplasia, with mitotic and amitotic nuclear divisions.

63. Sarcoma of the Uterus.

KLENDE (*Orvosi Hetilap*, 1919, 32, quoted in *Zentralbl. f. Gynäk.*, September 11th, 1920) records five cases of sarcoma of the uterus, of which two occurred at the age of 27, and three at ages 38 to 51. Three were cases of sarcomatous transformation of myomata. The author emphasizes the importance of submitting to microscopical examination all myomata removed by operation, and of giving prophylactic x-ray treatment. In cases in which x-ray treatment of myomata is not followed by the disappearance of symptoms, the existence of malignant changes in these tumours or in the pelvic organs other than the uterus should be suspected.

PATHOLOGY.

64. Histology of the Typhus Eruption.

BOMPIANI (*Arch. per le Sci. med.*, vol. 43, Fasc. 3-4, 1920), during an epidemic of typhus occurring in Rome in the summer of 1918 among the prisoners of war and the civilian population, made a histological study of the typhus eruption along the lines taken by Fraenkel. The results were as follows: Rose spots removed on the eighth, tenth, and fifteenth days of the disease showed the characteristic changes described by Fraenkel; they consisted of an accumulation of cells, of various dimensions and of a round or irregularly polygonal form, surrounding a vessel. These lesions were found most frequently in the reticular layer of the dermis, or at the junction of the dermis and subcutaneous tissue. In addition to the typical nodules described by Fraenkel large areas of diffuse infiltration (usually connected with a vessel) were found during the eruption period. At an advanced stage of the disease (twenty-second to twenty-seventh day) lymphoid nodules and fibrous nodules were found.

65. Peripheral Vasomotor and Pulmonary Reactions.

AZZI (*Lo Sperimentale*, Fasc. i-iii, 1920), as the result of observations on thirteen individuals, found that with the production of a peripheral vaso-constriction, as registered by Mosso's plethysmograph on the forearm, a diminution of the temperature of the expired air took place. These observations furnished confirmation of Galcott's hypothesis that variations in the temperature of the expired air depend on vasomotor changes. It was possible to observe the extreme sensibility of the vasomotor state of the respiratory organs to stimuli of various kinds, including emotion.

70.D

66. Tuberculosis of the Female Genitals.

ACCORDING to DRIESSEN (*Nederl. Tijdschr. v. Geneesk.*, October 23rd, 1920) 10 per cent. of all women with phthisis suffer from tuberculosis of the genitals. Infection may occur in one of three ways: (1) Ascending, by infection from without—for example, by tuberculous semen or dirty instruments; (2) descending, from the peritoneum or intestine; (3) haematogenous or lymphogenous. The Fallopian tube is pre-eminently the seat of tuberculous infection. Among 52 cases of genital tuberculosis Driessen found the vulva affected in one case, the vaginal portion of the cervix in one, the endometrium in 5 cases, and the Fallopian tubes in 45, or 86.7 per cent. Tuberculosis of the ovaries is extremely rare, being even less frequent than tuberculosis of the uterus: this has been attributed to the protection afforded by the tunica albuginea investing the ovary. In Driessen's opinion the monthly engorgement of the uterus and ovary plays an important part in their lesser susceptibility to infection, it being well known that during pregnancy (when this factor is excluded) tuberculosis is specially apt to develop.

67. Bacteriology of Influenza in 1918-23.

SINDONI (*La Pediatria*, September 15th, 1920), as the result of investigations in a large number of cases, came to the following conclusions: (1) Pfeiffer's bacillus gives rise to the formation of specific agglutinins in the blood of individuals who are actually suffering from the disease or have recently had it. (2) The agglutinin content of the blood appears on the fourth or fifth day of disease, increases during convalescence, and diminishes when the patient is cured. (3) The amoceptor behaves in a different way, as it is found most easily during the disease, is most difficult to find in convalescence, and disappears on recovery. (4) Pfeiffer's bacillus is almost constant in the nasopharyngeal mucus of influenza patients, and can be found both in smears and cultures. The organism was not found in healthy persons or in other respiratory diseases, nor was it detected in the small epidemics of influenza which occurred in previous years, especially in infants at the Palermo Pediatric Institute. Sindoni, however, does not consider that Pfeiffer's bacillus is the cause of influenza any more than that "X 19" is the cause of typhus.

68. Hypertension in Chronic Nephritis and Arterio-sclerosis.

CARNOT and RATHERY (*Paris med.*, September 25th, 1920), in addition to experimental evidence, bring forward the following clinical proofs of the necessity of a high blood pressure for maintaining the circulation and diuresis whenever the peripheral or renal resistance is increased. In the first place, arterial hypertension is necessitated by the exaggeration of the renal and peripheral resistance. This increased resistance is due partly to induration, rigidity, and perhaps a certain spasm of the vessels, and partly to increased viscosity of the blood. Secondly, if at a given moment, either spontaneously or as the result of treatment, the hypertension declines, while the resistance remains the same, the circulation and diuresis both fail. Thirdly, the production of hypertension by therapeutic measures—for example, digitalis—re-establishes diuresis.

69. Weiss's Reaction in Typhoid Fever.

WIGGELENDAM (*Nederl. Tijdschr. v. Geneesk.*, October 30th, 1920) regards Weiss's urochromogen reaction as of great value in the diagnosis of typhoid fever owing to its early appearance and simplicity. A specimen of the urine, appearance and simplicity. A specimen of the urine, filtered if necessary, is mixed with two to three parts of water and poured into two test tubes. Two or three drops of a 1 in 1,000 solution of potassium permanganate are then added to one test tube, and if the reaction is positive the urine assumes a bright canary yellow colour, in striking contrast with the urine in the other test tube. The reaction is not specific to typhoid fever, but may occur in advanced pulmonary tuberculosis and scarlet fever. This does not, however, detract from the diagnostic value of the reaction, as these diseases are not liable to be confounded with typhoid fever.

70. *Toxoplasma pyrogenes* Castellani in the Sudan.

CHALMERS and KAMAR (*Journ. Trop. Med. and Hygiene*, February 16th, 1920) have found in a splenic abscess, made post mortem, the bodies of *Toxoplasma pyrogenes* Castellani which Castellani, working in Ceylon, described in 1913. The patient died of a pyrexial disorder prevalent in an isolated port in the Sennar province of the Sudan.

PIONEERS AND EMPIRE BUILDERS: No. 104.
FOURTH PERIOD, circa 8000 to 2500 B.C.

When Pituitary Extract is indicated, use

TRADE MARK 'INFUNDIN' BRAND

PITUITARY (INFUNDIBULAR) EXTRACT

After preparation, and before issue, 'INFUNDIN' is subjected to physiological tests of exceptional stringency; any batch which fails to pass these is *destroyed* forthwith. A high and uniform degree of activity is thus ensured.

Although entirely free from any kind of preservative, reports show that 'INFUNDIN' has retained its activity for over six years.

Issued in hermetically-sealed containers of 0.5 c.c. and 1 c.c. in boxes of six. May be injected intramuscularly or given intravenously or per rectum in normal saline.

VESTIGES OF THE EARLIEST KNOWN FORM OF FIXED HABITATION IN EUROPE.—The Neolithic pioneers constructed dwellings in lakes, at a distance from the shore. Here they were safer than elsewhere from attack by man and the wild beasts which haunted the dense neighbouring forests. To make a platform on which to build their huts they first drove wooden piles into the mud at the bottom of the lake or marsh. The accompanying illustration shows the remains of one of the oldest of the lake settlements found buried in preserving peat at the bottom of a lake. Its piles, 10 or 11 ft. long, were of oak, beech and pine, sometimes whole, sometimes split, and sharpened at the end by fire or by stone celts. Other remains show that the platform consisted of cross timbers fastened to the piles by wooden pins. The outer borders of the pile structure were protected and bound by wattle and hurdlework of branches. Connection with the shore was established by a bridge constructed in the same manner. About 103,000 piles covered three acres of the Swiss lake in which was thus built a village which lasted and was inhabited for centuries after the first pioneers drove in the earliest piles. More than once the huts and portions of the substructure were burnt down and re-built.

An Address

THE PART OF THE PRACTITIONER IN THE
TREATMENT OF THE PRE-OPERATIVE
STAGE OF ENLARGED PROSTATE.*

BY

J. W. THOMSON WALKER, M.B., F.R.C.S.,

SENIOR UROLOGIST AND LECTURER ON UROLOGY, KING'S COLLEGE
HOSPITAL; SURGEON TO ST. PETER'S HOSPITAL.

In surgery it is always easy to be wise after the event. Prostatic surgery supplies us with many examples of this truth, and anyone who thinks out the cause of post operative disappointments and failures must at times regret that more care was not taken in the operative treatment.

The greater the experience I gain in prostatectomy the more I am impressed by the fact that many of the complications of prostatectomy are preventable by pre operative treatment. There are complications against which no provision can give immunity. We cannot, for instance, avoid the occurrence of pulmonary embolism in a practically clean case. We cannot avoid cardiac failure which occurs days or weeks after the operation, or renal failure when the kidneys have been destroyed beyond the point of recovery. But we can prevent or modify some of the bowel complications or kidney complications and some of the other complications by careful pre operative examination and preliminary treatment. And it is along these lines that the practitioner can do so much to help in reducing the mortality of prostatic enlargement.

The risks to which a patient suffering from enlarged prostate, whether he be submitted to operation or treated without operation, is exposed, are not confined entirely to the urinary organs. They may be arranged for discussion under different systems:

1. Gastro intestinal risks.
2. Pulmonary risks.
3. Circulatory risks.
4. Nervous system risks.
5. Urinary risks.

GASTRO INTESTINAL RISKS.

I will first relate a case of gastro intestinal complication following operation, and then discuss the subject.

A S. B., aged 60, complained of frequent micturition and neuritis of the right arm. He was known to have a high blood pressure (180), and had had his teeth removed as a possible source of infection for his neuritis. There had been several attacks of retention of urine during the past two years.

He was a stout, short necked man with a predominant abdomen. The frequency of micturition amounted to twenty minutes during the day and five or six times at night. There was urgency, hesitation at the commencement and difficulty in the act. The urine was clear, and there was about one ounce of residual urine. The urine contained only 1 per cent of urea, but the quantity was normal. The prostate was large, elastic, movable and prominent in the rectum. The kidneys were not palpable or tender. He showed no clinical signs of uraemia. His appetite was large, and there was a tendency to constipation. Flatulent distension of the abdomen was common after meals. Apart from the enlarged prostate, bowel distension, the high blood pressure and the low urea content of the urine, nothing abnormal was discovered by two physicians at different dates.

I was uneasy about the bowel, and declined to operate until he had undergone some treatment for the flatulent distension. He improved on bowel antiseptics, but pituitary gland did not suit him. After a month I saw him again and consented to operate, although I expressed some anxiety in regard to his bowel.

On June 10th, 1920, an adenomatous prostate weighing 56 grams was removed under spinal anaesthesia with a minimal amount of general anaesthetic. Haemorrhage was very moderate, and there was no shock. Post anaesthetic vomiting was moderate on the day of the operation, and had ceased next day. On June 11th the condition was good and much flatus was passed. The temperature was 99°. There was free drainage, the urine being stained with blood. During the day he complained of flatulence; pituitin (1 c.cm.) gave much relief, and flatus was passed freely.

During the night June 11th-12th flatulence was very troublesome, but was relieved by the rectal tube. The temperature was 99° and the pulse 83. The complaint of flatulence continued on June 12th and 13th, but on the 14th it had disappeared and on this day the bowels moved three times after an aperient.

* Part of an address delivered before the Brighton and Sussex Medical-Chirurgical Society on December 2nd, 1920.

On June 20th he was given some indigestible food by his relations. This was followed by vomiting and abdominal distension. These symptoms continued and now dominated the clinical picture. Urine was being secreted in good quantity. On June 20th he was seen by a physician, who diagnosed intestinal obstruction, and a general surgeon was called in consultation. The surgeon, however, agreed with me that there was no obstruction or peritonitis. Vomiting continued. The stomach was washed out, with some relief.

During the next ten days the distension varied; sometimes the abdomen was tense and at other times it was fairly soft. The bowels were opened by enemata with varying results, the motions being always very offensive.

On June 26th, 27th, and 29th the temperature rose to 100° and 101°. The quantity of urine, so far as could be measured, diminished slightly, but it was 37 oz. on the 28th and 33 oz. on the 29th.

On June 25th the blood urea was examined and found to be greatly increased (370 mg. in 100 c.cm.). There were no symptoms pointing to uraemia on June 27th, but next day there was some drowsiness and a good deal of wandering. On this day (June 28th) signs of cardiac failure appeared and became increasingly evident, and recurred during June 29th, and he died on June 30th.

I have quoted this case at length as it is a good example of the type of bowel complication that is likely to be met with after prostatectomy. In this case there was an element of anaemia (due to chronic interstitial nephritis), which is absent from most of the cases I have seen.

Post operative distension of the bowel may occur in all degrees of severity, from a slight flatulent distension with difficulty in getting the bowels moved for a few days after the operation to a prolonged distension of the bowel ending fatally from pressure on the diaphragm and interference with the heart's action. Rarely, it occurs as a very acute condition and is rapidly fatal.

One of the most striking cases I have seen occurred in a man of 60 of the same type as the last, in whom I removed the prostate and a bladder growth. He made good progress until the fourth day, when he suddenly had pain in the epigastrium; the abdomen became acutely distended and the distension continued for two hours, when he died of cardiac failure. I have not seen another case so acute.

This post operative distension in urinary surgery is not confined to prostatic and bladder cases. I have seen a similar condition which ended fatally after an operation for stone in the kidney, and distension of the colon is not uncommon during the first few days after kidney operations. It is seldom, however, that it is so serious as that following prostatectomy. I have seen it also in a case of septic stone in the kidney where no operation was performed.

In looking for a cause for the condition we must remember that in kidney operations the colon is stripped from its attachment to the kidney and below this, and there is sometimes a good deal of trouble in separating adhesions at the extraperitoneal aspect of the colon. When we remember also that in septic kidney conditions perinephritis is constantly present, and that this must involve the contiguous wall of the colon, there is no difficulty in recognizing that a local paralysis of the colon is likely to occur leading to distension with flatus which spreads to other parts of the colon.

In prostatic cases so simple an explanation is not possible. In most of those I have seen the colon is distended, and constipation and hicough are frequent, but in some cases the stomach is the organ affected, and the distension affects the upper part of the abdomen; in these constant vomiting of coffee-ground material is usually a symptom, and a large quantity of this fluid may be removed with the stomach tube.

Most of these cases are cases of enlarged prostate with back pressure on the kidneys, and in some of them, such as that which I have described, uraemic symptoms actually appear. It is likely, therefore, that uraemia may have something to do with causing the condition. But there are cases that occur in younger men without sepsis or back pressure, and, further, the symptoms and proof of renal inadequacy is absent in most of the cases.

Two elements, I believe, enter into the causation. One is flatulent distension of the bowel from intestinal fermentation, and the other is exhaustion of the sympathetic nervous system as a result of uraemia, intestinal toxæmia, or shock.

Recently it has been suggested that post operative dilatation of the stomach is due to dragging on the

mesentery by the small intestine dropping into the pelvis after the removal of large pelvic tumours (Borchgrevink).

Having recognized that such a condition may complicate prostatectomy, is it possible to foretell its occurrence and do something to prevent it? It is, I believe, possible to do so.

There are two different types of patient that are liable to this condition—a thin type and a stout type. Imagine a thin man of 60 with a sallow complexion. He complains of prostatic symptoms; the prostate is enlarged, and there is a varying amount of residual urine. Further investigation shows that he suffers from flatulent indigestion after meals, and has to be careful about his diet; his teeth are probably decayed and there is pyorrhoea; the tongue is coated. The abdominal wall is thin, and should lend itself to easy palpation but that the bowel is full of gas, the percussion note tympanitic, and abdominal palpation is difficult. The other type is a stout, flabby man of 50 or 60, often of the Jewish race. He is fond of rich fatty foods, and is immoderate in his indulgence in them. The abdomen is prominent, rounded, and tense; there is no pyorrhoea or decayed teeth. When you meet with an enlarged prostate with either of these types you may expect post operative trouble from the bowel.

How can we prevent this complication and how treat it when it occurs?

In all such patients I recommend a course of four or five weeks' bowel treatment after the teeth have been carefully overhauled. This question of teeth is very important; it affects not only the bowel risks, but also the pulmonary risk. Oral sepsis is the cause in some degree, if not wholly, of the flatulent dyspepsia of the first type of case. It may take five or six weeks or even longer for the dentist to treat the oral sepsis, and there may be considerable difficulty in getting the patient to consent to the dental treatment, but the matter is so important that it is the duty of the doctor to insist on the mouth being clean before any operation is performed. Anaesthetists will, I think, support me when I complain of the condition of the mouth and teeth in many patients who come up for operation, not only in hospital but in private practice. I do not think that practitioners sufficiently appreciate the serious menace that such a condition is to a patient about to undergo an operation.

All these intestinal-risk patients, however, do not have decayed teeth and pyorrhoea and the second type very often have good teeth. The bowel itself must therefore be treated.

I do not presume to instruct such an assembly as this in the treatment of flatulent dyspepsia. Let me mention, however, the lines of treatment that have been most successful in the prostatic cases I have seen. They are the restriction of starchy foods and green vegetables in the diet, bowel antiseptic treatment, and bowel tonic treatment. A capsule containing β -naphthol 5 grains, salol 5 grains, and calomel $\frac{1}{2}$ grain has proved a good combination, and capsules of kerol (intestinal) are very valuable. At the same time the bowels must be regulated by vegetable aperients. I do not consider salts and aperient waters suitable for these cases, for they tend to cause distension of the bowel with gas. Tonic treatment of the bowel should be combined with these measures. Strychnine and ergot are the best drugs, and suprarenal and pituitary extracts act as powerful tonics of the bowel muscle.

Two other methods of treatment have been of much use in these cases—namely, abdominal massage and electrical treatment of the bowel. One would, of course, not think of employing either of these methods where the bladder is known to be distended with residual urine.

Now let us turn to the post-operative treatment. In the average patient the immediate preparation of the bowel for operation consists in giving a dose of castor oil two nights before the operation and washing out the colon on the morning of the operation. After the operation the bowel is left quiet for three or four days, and then a dose of castor oil is given. This is done in order to avoid straining after the operation, which sometimes causes bleeding.

If, after the operation, the patient commences to show distension of the abdomen or vomiting of dark coffee-ground material, a purge (castor oil) must be given at once.

In some cases the stomach is distended and there is

persistent vomiting. Here the stomach tube should be passed, and the stomach washed out. Sometimes large quantities of dark brown fluid are removed and the washing will have to be repeated.

Borchgrevink, who looks upon dilatation of the stomach after abdominal operations as due to dragging on the mesentery causing obstruction at the duodeno-jejunal junction, recommends the prone position and elevation of the pelvis; and operation has been recommended with the object of raising the intestines from the pelvis and relieving the drag on the mesentery, and also of removing adhesions. I have not met with a case of post-prostatectomy distension where this procedure held out any prospect of success.

The more common cases have distension of the colon and hicough, but no vomiting. Pituitary gland is a good drug in these cases, but it should be given carefully on account of its effect on the blood pressure; $\frac{1}{2}$ c.cm. may be given at first and repeated in a few hours, and 1 c.cm. given daily. Ergot and strychnine may also be given.

A high rectal tube should be passed and the colon washed out and a tube left for several hours at a time in the rectum. When the patient is stout, he should be made to lie on his side instead of being propped up in a sitting position, as the passage of flatus is facilitated by this position. Various enemata are given—soap and water, ox-gall, turpentine. Care is necessary in giving enemata of turpentine in old feeble patients. In a hospital patient I once saw sloughing of the whole thickness of the rectal wall in a circular cuff following a large turpentine enema.

PULMONARY RISKS.

There are two pulmonary risks that should engage the attention of the practitioner before the operation. One is the possibility of post-operative pneumonia and the other is bronchitis.

Most cases of post-operative pneumonia that I have seen when the patient has not been exposed for a long period at the operation were due to septic teeth, or to some septic condition of the nasal sinuses. These sources of septic pneumonia should be most carefully treated before the operation of prostatectomy is undertaken. It is sometimes urged that the operation is urgent and must be done without delay. There is nothing to support this view. It may be, and often is, urgently necessary to drain the bladder on account of sepsis or obstruction, but this can be done under local anaesthesia and the prostatectomy deferred until the patient has got rid of the oral or nasal sepsis.

Chronic bronchitis requires careful pre operative treatment. A patient with bronchitis after prostatectomy, or, indeed, after any abdominal operation, is in a very serious state. Coughing is very painful and difficult, and the patient is apt, even in the sitting posture, to become water-logged from inability to expectorate. Pre-operative treatment may include courses of vaccine and even climatic treatment before the patient is fit for operation.

Chronic bronchitis is not infrequently combined with obesity and a fatty heart, and those patients are very grave risks for prostatectomy. Certain modifications of the operation should be made in order to lessen the risk in these patients. Spinal anaesthesia is used as an anaesthetic, the Trendelenburg position is avoided, and the patient is kept sitting up in bed after the operation.

I have tried prostatectomy under local anaesthesia in such cases, but have not been favourably impressed by the method. Cystotomy is easily carried out under local anaesthesia without the patient suffering pain or even discomfort, but I have found that even the most careful preparation of the bladder, urethra, and prostate with local anaesthetics is not sufficient to abolish the pain of enucleating the prostate, tearing across the urethra, and removing the gland from its bed.

Pronounced spinal curvature, whether due to old spinal caries or to other causes, is a grave pulmonary risk. One of the greatest risks I have taken, and one which I am glad to say was justified by success, was the case of a well known member of our profession who suffered from advanced osteitis deformans, and in whom the spinal curvature was so extreme that the ribs met the iliac crests on each side. The chest was rigid, and respiration was purely diaphragmatic. Yet he underwent a severe operation for growth of the bladder, and lived without recurrence for some years afterwards.

CIRCULATORY RISKS.

Circulatory risks are probably the most difficult of any to estimate where prostatectomy is proposed. There are some that are much reduced by careful treatment. Two of these deserve mention—namely, high blood pressure and cardiac insufficiency. With high blood pressure we expect post-operative haemorrhage. These patients usually stand haemorrhage very well, but a haemorrhage severe enough to cause a sudden drop of blood pressure may end fatally. Any hope of permanently reducing the blood pressure before operation is certain to lead to disappointment, but much can be done by rest, careful diet, removal of stimulants, and attention to the bowel, and a careful course of such treatment for a month before operation will well repay the time spent. I recently operated on a patient when the blood pressure was the most important factor in the case. The case was as follows:

A gentleman, aged 62, consulted me in October, 1920. He complained of frequent micturition night and day. There were recurrent attacks of difficult micturition, during which there was *spasm of the bladder and severe straining*. He had been catheterized, and this had been followed by a rise of temperature. The urine contained a small amount of mucus and very many micro-organisms. The blood pressure was 190 to 200 mm. Hg. In January, 1919, he had a slight attack of hemiplegia. The intensity of the spasmodic attacks suggested the possibility of some cord lesion.

He was a spare active man with a moderate enlargement of the prostate and no residual urine, suitable for prostatectomy, but with circulatory and nervous risks. Sir Thomas Horder examined him and reported that there were no signs of cord changes, but that definite traces of left hemiplegia still remained. The blood pressure was high, but Sir Thomas Horder agreed with me that there was a circulatory risk in not operating from the severe straining during the recurrent attacks of obstruction.

Operation was decided upon, and the following points were made in regard to the anaesthetic: Gas and oxygen and also ether were avoided on account of the effect on the blood pressure. The Trendelenburg position was precluded from the effect it would have on the cerebral circulation. The anaesthetic chosen was spinal anaesthesia with stovaine.

The operation passed off smoothly. There was one small haemorrhage after the operation, but it was easily controlled. The patient made a good recovery.

I have operated on patients suffering from the various forms of valvular disease of the heart, and also in a case of thoracic aneurysm, and have not had any trouble so long as compensation was good. If the patient can walk quickly and go upstairs without breathlessness, and can go about his ordinary duties without cardiac pain or other sign, there is apparently nothing in a valvular lesion to contraindicate prostatectomy.

When the blood pressure is high ether is better avoided, and in most cardiac lesions the Trendelenburg position should be avoided as far as possible. Spinal anaesthesia, with a very small amount of C.E. and oxygen, seem to suit these patients. In choosing the anaesthetic, the profound drop in the blood pressure, as the result of spinal anaesthesia, will of course be taken into consideration.

Anaemia is a further risk. The risk is partly operative and partly post-operative. These patients do not stand loss of blood at the time of the operation, and they are less likely to survive post-operative complications, such as bronchitis, bowel distension, exacerbation of pre-existing sepsis, etc. Moreover, they heal very badly. The wound fills with weak oedematous granulation. Closure of the bladder is delayed and a fistula may persist.

Bransford-Lewis, in discussing the importance of anaemia in prostatectomy, states that haemoglobin, about 60 per cent., is favourable, 50 per cent. justifiable, 40 per cent. is unfavourable, and 30 per cent. fatal in prostatectomy. Without making any such hard-and-fast rule, I feel that there should be very careful consideration of this risk before operation, and that treatment should be directed to removing it.

Anaemia in these cases usually results from chronic sepsis, and the treatment must be directed primarily to removing this. In the great majority of cases the sepsis is in the urinary tract, and the patient is suffering from what is termed urinary septicaemia—a combination of uraemia from obstruction and toxæmia from chronic cystitis and pyelitis or pyelonephritis. In such cases the proper treatment is free drainage of the bladder by cystotomy. The removal of the prostate is postponed until the sepsis has cleared up and the haemoglobin content of the blood has improved. A two-stage operation is thus carried out.

Treatment of extra-urinary sources of sepsis should also be carried out. Alveolar abscesses, pyorrhoea, septic tonsils, sepsis of the accessory air passages, chronic appendicitis, cholecystitis, are some of these extra-urinary foci of sepsis that require treatment before prostatectomy is undertaken. Further, direct treatment of the anaemia should be undertaken. The question of transfusion of blood should, I think, be raised in these cases, and I am strongly of opinion that in selected cases this should be carried out before undertaking prostatectomy.

NERVOUS SYSTEM RISKS.

The question occasionally arises whether a patient suffering from tabes or multiple sclerosis should have an enlarged prostate removed.

The diagnosis is extremely difficult. There is an adenomatous enlargement of the prostate and signs of tabes. The point that at once arises is, what is the condition of the bladder wall? Is the residual urine that is present due to atony of the bladder wall or is it due to prostatic obstruction?

The following points are of importance in differentiating between nerve atony and obstruction. In atony of the bladder from nervous disease nocturnal incontinence is an early symptom. It appears sometimes before the other symptoms of nervous disease are noticed, and it should be a rule that whenever an adult male complains of nocturnal incontinence without other symptoms, tabes should be suspected, and a careful examination of the nervous system, including of course examination of the spinal fluid, made.

Incontinence of urine occurs, of course, in enlarged prostate, but not unless the bladder is distended and the leaking urine is an overflow. In tabes, on the other hand, incontinence occurs where only a few ounces of residual urine are present.

In enlarged prostate frequency of micturition is a prominent symptom, especially nocturnal frequency. This is often absent in tabes and there may be a lack of desire rather than increased frequency. Where cystitis is present, however, there will be frequent micturition in tabes.

The time of onset of bladder symptoms may have been before the prostatic age—namely, after 50 years.

On passing a catheter, the force of the stream through the catheter is much more powerful in enlarged prostate than it is in tabes.

Cystoscopy shows changes in the bladder in tabes that are quite typical of the "nerve bladder." The whole bladder wall is covered with thin, sharp trabeculae, crossing and recrossing each other, and between these are multitudes of sacculi. The trigone is not affected.

In the obstructed bladder the trabeculae are thick and fleshy, and sacculi only appear in the late stage, and are comparatively few in number. The trigone is involved in the trabeculation, and it may be difficult to recognize the interureteric bar and find the ureters. In multiple sclerosis the symptoms are those of a spasmodic bladder, and the diagnosis is more likely to be confused with cystitis. There is frequent micturition amounting to strangury, active incontinence at night, and sometimes also during the day, no residual urine, and the urine is clear.

When in a tabetic subject the residual urine is due to enlarged prostate prostatectomy will give a brilliant result. In such a case there is a danger of bedsores developing during convalescence, but this can be avoided by careful nursing. I have performed prostatectomy three times on patients the subject of advanced disease of the spinal cord—twice in tabes and once in multiple sclerosis—and in all with success, the vesical function being completely restored to its normal condition.

Another problem connected with the nervous system is operation on patients suffering from enlargement of the prostate who have had hemiplegia. This problem is connected also with the circulatory system, and I have discussed it under that system.

URINARY RISKS.

Of all the risks to which the sufferer from enlargement of the prostate is exposed, those connected with the urinary tract are the most common, and also the most frequently fatal. These risks are, however, the most amenable to pre-operative treatment. They are sepsis and renal inefficiency.

A very large number of the patients that come to the surgeon are already infected and are suffering from the effects of back pressure on the kidneys. They are passing through a danger period which may be of recent onset or may have existed for some months or even years. Operation on such patients frequently gives very brilliant results. Patients who are broken down in health, unable to attend to their business or social duties, may, after prostatectomy, make a striking recovery and return to their duties active and rejuvenated.

But there is another side to the picture. The mortality in such cases is high. Some of these patients die under treatment before an operation is performed, others die from the operation because it increases the septic absorption or overturns the already much disturbed balance of renal secretion, and others, again, while temporarily improved by operation, gradually go downhill from the continued sepsis and progressive renal failure. It may be said, therefore, of cases of enlarged prostate suffering from sepsis and renal failure that the condition of the patient is very grave and will eventually be fatal without operation, that the mortality of operation in such cases is high, and that the duration of life in most cases that survive operation is shortened.

Is it necessary that patients should be allowed to pass through this period of danger before being relieved by operation? I hold that it is not, and I think most surgeons who do much prostatic work will agree with me that operation should be performed early in order to avoid this period of danger and its after-effects.

The remedy lies almost solely in the hands of the general practitioners. If they bring the patient up for operation in the early stage, before the bladder has been infected by the catheter and before the kidneys have been injured by the continued back pressure, this danger period can be avoided. There are, of course, some patients who refuse to submit to operation until they are convinced by the sufferings entailed by catheter life that it is inevitable.

The result of the operation in an early case is not so striking as in a case where the patient has suffered from urinary septicaemia, but after operation his prospect of life is better than even the most brilliant case of recovery from urinary septicaemia.

The practitioner should be prepared to make a diagnosis of enlarged prostate before an attack of retention has occurred.

Frequency of micturition is usually the earliest symptom. It may be the only symptom even when the prostate has reached a considerable size. There is a curious belief prevalent among the male public that increased frequency of micturition and nocturnal frequency is a normal accompaniment of advancing years. Nothing could be more erroneous. The senile bladder is, if anything, less sensitive than the young bladder, and any persistent increase in the frequency of micturition, nocturnal or diurnal, is pathological, and requires careful investigation.

Rectal examination may disclose, even in the early stage of the symptoms, a large elastic prostate. On the other hand, there may be a doubt as to whether enlargement is present. In such a case we must remember that the prostate enlarges in two directions—namely, outside the bladder, extending backwards into the rectum, and upwards into the bladder. There may be intravesical enlargement with very little change that can be detected *per rectum*. The next step, therefore, is cystoscopy, and at the same time an estimate will be made of the residual urine.

Where difficult micturition is the chief symptom, the degree of obstruction varies with wide limits, and I can best discuss it by giving three types.

TYPE 1.—*The patient with chronic retention of urine and partial renal failure, or uraemia.*

The patient can pass water with a fair stream, but he has pronounced nocturnal frequency and sometimes nocturnal incontinence. He usually complains of headache and thirst, and sometimes the latter is a prominent symptom. The tongue is dry and glazed, the appetite poor, and the bowels constipated. The patient may be losing flesh, but he sometimes says he is getting stouter, the fact being that the distended bladder increases his girth. On examination there is a distended bladder reaching

almost to the umbilicus. On rectal examination the prostate is enlarged and elastic. There is no more dangerous class of case in urinary surgery than this. A careful survey of all the symptoms is called for in order to estimate fully the probable danger points under treatment.

Finally, the condition of the kidneys should be carefully investigated. I have already indicated the symptoms of renal failure or uraemia. One of the tests of the renal function should be added to make the picture complete.

The most easily applied of these tests is called the urea concentration (MacLean) or forced urea elimination test, and there is no reason why the test should not be used by every practitioner. A dose of 15 grams of urea is given by the mouth, and the patient at the same time directed to empty the bladder as far as he can. The urine passed in the first hour is collected as a specimen, and that passed in the second hour after administration of the urea is collected. The urea is quantitatively estimated by the ordinary method. The normal kidney will excrete 2 per cent. or over, a damaged kidney between 1 and 2 per cent., and a seriously damaged kidney under 1 per cent.

I will pass now to the treatment of such cases.

The two cardinal points in the management of such a case are to avoid infecting the bladder and to empty the bladder very slowly. A distended bladder is much more easily infected than a normal bladder, and the slightest mistake in technique will be followed by some cystitis, which in such cases quickly leads to ascending pyelonephritis and death. When there is chronic distension of the bladder the kidneys are working against very high pressure. If the bladder is rapidly emptied, the sudden fall of pressure leads to a rush of blood into the renal vessels and suppression of urine very often supervenes.

Such are the dangers. How can they be avoided?

In the first place, there must be no hurry to pass a catheter without adequate preparation. The condition has been going on for many months, if not for years, and a few days longer will make no material difference. Therefore, put the patient to bed, keep him warm, get the bowels well cleaned out, give him urotropin and as much fluid as he will drink.

After a few days, under the most rigid aseptic precautions, pass a coude catheter, No. 8 or 10, and tie it in the urethra. Withdraw 10 oz. and plug the catheter. Get the nurse, very carefully drilled in asepsis, to withdraw 10 oz. every hour until the bladder is empty. Now attach a small rubber tube to the catheter and allow the urine to drain away continuously into a bottle. All the time continue the urotropin and large quantities of fluid and keep his skin acting by a warm temperature and hot bottles.

The danger period lasts usually a week or ten days, and during that time continuous drainage of the bladder must be kept up. One or two tests of the renal function during this period will show the functional condition of the kidneys. The clinical symptoms are a very important indication also.

With improvement the thirst diminishes and is lost, the tongue becomes moist, the appetite improves, and the headache disappears. On the other hand, persistence or increase of these symptoms is a grave indication. To these may be added drowsiness during the day and wandering and restlessness at night. The patient tries to get out of bed.

At the end of ten days or a fortnight what is to be done? If the patient has improved under the drainage, and the renal symptoms have disappeared, operation may be undertaken. If the renal symptoms have continued and increased, the bladder should be drained suprapubically under local anaesthesia, or gas and oxygen, and the patient must wait until the renal function has improved before the prostate is removed. It is sometimes necessary to wait for many weeks or even months before the patient is ready for prostatectomy. If the period is prolonged, a suprapubic apparatus should be fitted and the patient allowed to go about.

It will sometimes happen that the facilities for carrying out this programme of draining the bladder are lacking. In this case, and unless you are absolutely satisfied that you can conduct the case with safety from sepsis, it is far better to place the patient under the surgeon at once without passing any instruments at all.

TYPE 2.—*The patient with frequent micturition, difficulty, and a well-marked enlargement of the prostate, and about 6oz. or 8oz. of residual urine.*

It is obvious that an operation will have to be done or catheter life commenced. In such a case the decision should not be left until an attack of retention has occurred. The danger of the catheter, whether it is passed as an emergency for the relief of an attack of retention or whether it is used regularly to remove residual urine, is that sepsis is inevitable. The result of introduction of bacteria is cystitis, and this is immediately followed by ascending pyelonephritis or surgical kidney.

After ten or fourteen days the attack usually subsides, but the urine remains cloudy. Recurrent attacks occur after fatigue, constipation, exposure to cold, dietetic indiscretion, and such causes, and it becomes apparent that the patient is gradually going downhill. The condition that we know as urinary septicaemia is developing.

In the great majority of patients on catheter life, whether they suffer from urinary septicaemia or not, there comes a time when, from increasing difficulty in passing the catheter or from haemorrhage or pain in passing it, catheterization is no longer possible and an operation must be done.

I have already stated my view that patients should never be allowed to get into this condition, and that early operation should be performed in order to avoid it. If infection has already occurred and urinary septicaemia has developed, the first aim of treatment should be to get rid of the combined back pressure and sepsis. This is done by draining the bladder.

A suprapubic cystotomy is performed under local anaesthesia or under gas and oxygen, and the patient is given large quantities of fluids and hexamine or salol. Rectal administration of saline may be necessary, for the patient may be unable to take sufficient fluid by the mouth. At the same time the bladder is flushed by constant irrigation through a catheter tied in the urethra and a Hamilton Irving suprapubic box.

Removal of the prostate is deferred until the urine is sufficiently clear and the tests of the renal function are satisfactory and the symptoms of uraemia and sepsis have disappeared.

TYPE 3.—*The patient complains of a little difficulty in starting micturition, and may get up several times at night. The prostate is found to be very large and elastic. There may be little residual urine.*

In this class of case the patient has difficulty in realizing that an operation is necessary. He objects, as he puts it, to having an operation done when he is quite well. He is, however, in a dangerous position. At any time, from slight causes, such as fatigue, chill, etc., he may have an attack of retention, necessitating the passage of a catheter under difficult conditions, with the possibility of septic infection, or he may gradually develop the condition of chronic retention of urine, with back pressure effects in the kidneys, that I have described. These issues should be clearly placed before him and an operation recommended to prevent them.

There is another outcome which you do not hear very much about. An adenomatous prostate occasionally becomes malignant. There are, I find, two types of malignant prostate with which we have to deal. In the one the prostate is hard, nodular, and fixed, and the change has evidently been malignant from the commencement; in the other there is an elastic adenomatous prostate, which at one part is hard and leathery and becoming fixed. Further, there are some cases in which an enlarged prostate, adenomatous on rectal palpation, shells out easily and completely, but the pathologist reports that at one part in the gland the appearances are those of a malignant growth.

This malignant development does not take place in a large percentage of cases, but it is met with sufficiently often to make it necessary to consider it in estimating the prognosis of a case of enlarged prostate treated without operation.

INDICATIONS FOR OPERATION.

In discussing the question of operation as opposed to catheter life with your patients, I would like you to consider the following points:

1. Enlargement of the prostate is a progressive disease, the rate of increase of which we cannot foretell.
2. As the prostate enlarges, the patient grows older, and is less able to withstand the effect of uraemia or sepsis, or the effects of a severe operation.
3. When the symptoms become acute, much damage has already been done to the kidneys; and although improvement may follow operation, much of the damage is permanent.
4. Some adenomatous prostates become malignant.
5. The mortality of catheter life is higher than that of prostatectomy.
6. A very large proportion of the cases of enlarged prostate treated by catheter are forced eventually to undergo operation.
7. The prognosis in such cases is much graver than if the operation had been performed without a period of catheter life.
8. A large proportion of the deaths after prostatectomy are due to the sepsis caused by pre-operative catheterization or the back pressure and renal inefficiency due to delay in submitting to operation.

THE TEACHING AND STUDY OF HUMAN ANATOMY.

BY

RICHARD J. A. BERRY, M.D., F.R.C.S.,
F.R.S. EDIN.,

PROFESSOR OF ANATOMY, INCLUDING HISTOLOGY, IN THE
UNIVERSITY OF MELBOURNE.

CONTRARY to currently accepted opinion, human anatomy is not a study of the dead, but of the living. It merely utilises the dead as a partial and imperfect means to an end. That end seeks to establish the essential foundations upon which the practice of medicine is based, and hence the place of anatomy in the medical curriculum. It is not a thing apart from the curriculum, but belongs to every part of it. Anatomy also endeavours to promulgate the welfare of peoples by the study and interpretation of the biological laws of life. The former is the particular province of the student of medicine and the surgeon, whilst the latter belongs more exclusively to the professional anatomist. It should, however, be the aim of both to correlate the study of life with that of disease, and hence anatomy, as a part of the medical curriculum, should lead up to the study of medicine and surgery. If anatomy fails in either or both of these objects it can hardly expect either the recognition or the prominence in our curricula to which it is really entitled.

That anatomy has too long been regarded and treated as a study of the dead is only too probable. Its textbooks and teachings still reflect the multiplicity of detail of the mid-Victorian period, but do so in an even more aggravated form; whilst the divorce from the clinician is more complete to day than at any other period in the history of medicine. If anatomy is to be taught to medical students on purely academic lines apart from hospitals and the study of disease, in water-tight compartments of medical curricula, and with examinations which are mere feats of memory, so long is it certain that as thus taught, crammed, and forgotten, it subserves no useful purpose in the study of disease.

This conception of anatomy as an academic study of the dead has resulted in an over-accumulation of largely unimportant detail. The unfortunate student of medicine is unable to differentiate between the vital and the useless. To him articulations of carpal bones are of equal import with lymph glands, probably more, because he can see the former and very seldom sees the latter. Relations of trivial arteries—which the surgeon seizes and ties—are matters to be learnt by rote, and bulk, in the student's eyes, as largely as great veins, epiphyses, and lymphatics. Muscles are studied with a meticulous attention to trivial details of osseous attachment, but with no conception of their collective functions in the living subject. Swamped in a morass of detail the student can no longer see the distant tree of knowledge for the mud.

Man is an animal—a highly specialized one in some directions, much less so in others. In his bodily structure and functions he conforms in every detail to the great and

universal laws of nature, and hence the student of anatomy must understand these laws and realize that they are the laws of the living and not of the dead. Anatomy is not, therefore, merely a study of structure. It is rather a study of the modification of structure to function, of impairment of function, and of the different vital conditions under which these functions are carried out. Properly interpreted, such a study leads logically and inevitably to an understanding of the phenomena of life as well as to those of disease. Its teaching necessarily implies a wider vision than is to be obtained from the dissecting-room cadaver, and compels from the expert some general acquaintance with embryology, histology, biology, and anthropology. A knowledge of medicine and surgery goes without saying. In this conception of anatomy there is little room for petty details of structure, but there is an immense field for observation, study, research, and quickened interest.

Of the many thousands of students whom it has been my privilege to teach I have never yet met one who has displayed the smallest interest in the purely anatomical construction of, say, the human shoulder-joint. Show the same man, however, that this generalized structure pervades the whole vertebrate kingdom; that modifications of this structure necessarily occur in different animals according to the specific purposes to which the limb is put; that man is no exception to this law, but that his shoulder-joint is also modified for man's particular purposes, and that this modification necessarily means a liability to frequent dislocation, and that once it occurs muscular action will play an important part in the subsequent events of diagnosis and treatment—then that student's acute interest is not only aroused, but his reasoning powers are stimulated, his memory is quickened, and his observational powers are directed to the fact that he himself possesses a shoulder-joint. He has thus travelled a long way on the path of truth—the path that leads to the living and not the dead.

Take, again, the arch of the aorta, with its long list of anatomical relations. Their acquirement by mnemonics, rather than by reason, is but empiricism. On the other hand, show the student, if possible, a case of aneurysm of the aorta; explain the physical laws which underlie the occurrence of aneurysm of the aorta and of the popliteal artery; demonstrate that all the clinical phenomena of aneurysm are wholly referable to pressure on anatomical structures; elicit from the student which of the aortic relations must be so pressed upon, and why, and what follows, and a totally different and more lasting impression is made upon the mind of the auditor than can possibly be made by a mere recital of names.

The human hand and foot, taught from a basis of evolution, embryology, and morphology, leading on to function, and through function to a loss of function—that is, disease—is an altogether more useful and profitable business than any mere collection of osseous articulations, muscular attachments, and relations of trivial arteries. The central and autonomic nervous systems also furnish—as do, indeed, almost all parts of the human body—many splendid instances of the real conception of anatomy as a study of the living. That anatomy can no longer be regarded as mere details of the dead is amply proved by this last system. Dissections on the cadaver—even the most careful—display but one portion of the autonomic nervous system, namely, the vertebral sympathetic, and not even the whole of that. If this be the limits of the student's horizon it is not humanly possible for him to acquire any adequate knowledge of the structure and functions of the whole of this important system. Doubtless physiology will assist him, but his naked-eye anatomy will not. Similar remarks apply equally well to the central nervous system, to the surgically important epiphyses and lymphatics, and to muscular actions and control. If anatomy is not to lead to a study of life, and through life to disease and its treatment, its failure must be writ large across the page of medical history.

Passing in the next place to points of more technicality but of less importance, human anatomy is suffering rather badly at the moment from its nomenclature. That nomenclature is out of date, and requires urgent and prompt revision. To squabble as to whether we shall employ the Basle anatomical nomenclature or revert to the still more antiquated "old terminology" is to serve the science badly. The latter is hopeless confusion and the former is already out of date. There is no room in the anatomy of

the living for anything but an accurate, scientific, and biological nomenclature which, within limits, shall be equally applicable to embryology and morphology. Such terms as "anterior" and "posterior" should give way to "ventral" and "dorsal," nor is there any scientific justification for the retention of such names as "inferior epigastric artery," as the artery is not "inferior" in any other animal but man. It is also open to question if we are justified, in view of modern neurological knowledge, in speaking of "branches of distribution" of both afferent, and efferent peripheral nerves. These criticisms notwithstanding, we owe much to the labours of the Basle International Commission, amongst other things the elimination of nearly 25,000 useless synonyms from the already long list of the names of gross anatomy. That the Commission's work is now out of date is undoubted, and there is urgently wanted a new commission of English-speaking anatomists, physiologists, and clinicians to determine the main principles to be adopted in the nomenclature of known facts, leaving details to a smaller committee of the Commission. As anatomical nomenclature concerns the whole medical profession, it would be well for clinicians to be consulted. Much of the opposition towards the Basle nomenclature has arisen from ignorance of the principles involved, and from the fact that it was largely a purely anatomical commission. With the main principles determined, a smaller and permanent committee of, say, the Royal Society, is required to determine from time to time the terms to be employed for the new facts discovered by research. Recent work on the autonomic nervous system is a conspicuous example of the confusion which is arising from the chaotic and improper use of terms and expressions for which there is no official sanction and but little foundation in fact.

That anatomical textbooks abound in a mass of detail, with little or no reference to function, and much of it of no importance, is easily verified by consulting them. Let one example suffice. The pectoralis minor muscle will be found described with the most faithful attention to the minutest points of its attachments. Why any student should be expected to burden his memory to the exclusion of his reasoning and observational powers with such verbiage—one had almost said garbage—is difficult to understand. From the standpoint of biology they do not elicit the important truth that, in man, the muscle has undergone retrogression from its more functional condition in the bird, which is in accordance with the great evolutionary laws underlying modification of structure to function; whilst from the standpoint of surgery the only important fact about the pectoralis minor muscle consists in its general relation to the ventral axillary wall, and to this, curiously enough, the student's attention is not directed by his textbook. Could not, then, much useless detail be eliminated from our anatomical textbooks, thus making room for facts of greater interest and wider applicability? Personally, I think it not only could but should, though conscience compels me to admit that I have myself been guilty of much which I also condemn. The real truth is that without the active co-operation of the clinician it is impossible for the anatomist to know how far he may proceed with safety in the elimination of the unnecessary. It should, however, even now be the plain duty of the teacher to tell his students where, how, and why much of this detail can be dispensed with.

The limited conception of anatomy as a study of the dead has also tended to limit the field of research, as has also that other conception that anatomy is restricted to the study of Man. Its aim is undoubtedly Man, the living man, but its foundations are to be sought in the study of all vital phenomena. The fields of heredity, morphology, and physical anthropology offer great and unrestricted possibilities to the anatomist of the living. The human cadaver offers few such fields.

This conception of human anatomy as a study of the living and not of the dead—if it be the true one, as experience leads me to believe—necessarily implies some drastic and revolutionary changes in its mode of teaching, in its place in the medical curriculum, and in the position of the laboratories in which its study should be prosecuted. The last mentioned should be as intimately associated with a hospital as is possible. If that be not possible, then much of its higher teaching should be conducted in a hospital with the aid of a projection apparatus, the living subject, and the clinician. Its study should not be restricted to

certain terms of the curriculum, but should be spread over most, if not all, the terms of that curriculum, and should be directly linked up in the form of team work with other subjects such as medicine, surgery, obstetrics, neurology, and the special senses. The actual dissecting can be completed in the earlier years of the curriculum with the elimination of much of the useless detail with which it is now encumbered. The supervision of this earlier part of the work can be safely entrusted to junior surgeons and recent graduates. Its higher and later study should be in the hands of the professional anatomist, who should himself be a member of the staff of the hospital in which his teaching and researches will be conducted. Under such conditions—which are not so Utopian as to be impossible of realization—the subject, the profession, and the patient would benefit enormously.

It may be argued that the extended field of observation which is here urged as being the province of the anatomist is altogether too large. That this is not so is shown by the number of living men who, in both their teachings and their writings, very efficiently cover this wider domain. What is more to the point is where such men are coming from in the near future. The social outlook has been so profoundly modified by the economic consequences of the Peace as to make it certain that no young medical man of promise and ability will nowadays willfully or deliberately choose the life of denial which, on existing salaries, will be his only reward as an academic teacher of medical science. Neither the universities nor the profession need expect the advancement of medicine by research if the emoluments of such research are to compare none too favourably with the daily wage of the manual labourer. The caustic critic—himself possibly paying supertax—need not regard this as a personal "grouse." It is a very genuine fear for the future of a branch of medical science to which every practitioner owes so much.

To many the ideas herein expressed will doubtless appear heterodox and revolutionary. On the other hand, a recent visit to England has convinced me that there is a much larger number who are very cordially in agreement with the main conception of this paper, which is that anatomy is a study of the living, and that its methods require modification. It is perhaps unnecessary to adduce evidence of the thesis, but it may be well to point out that the pages of *Medical Education in Europe*, published in 1912 by the Carnegie Foundation for the Advancement of Teaching, contain ample evidence of the fact that an anatomical institute should be in close co-operation with a hospital. The recently published report on the medical curriculum by the Edinburgh Pathological Club is similarly convincing as to the impossibility of teaching human anatomy in a water-tight compartment of that curriculum. The discussion at Cambridge in June, 1920, on the preliminary medical sciences—and particularly the eloquent words of Sir George Newman and Professor Arthur Keith—intensifies the necessity for change in the relations of the ancillary sciences to medicine. As Osler remarked, "Biology teaches the problem of life at every point, and may claim, as no other science, completeness of view and a comprehension which pertains to it alone." This is verily the living anatomy herein advocated, as is also Keith's dictum that "Anatomy could be made a living practical part of medicine." Why is it not?

A NOTE ON THE USE OF ANTIGONOCOCCAL SERUM.*

By FRANCES IVENS, M.S.LOND.,

HONORARY MEDICAL OFFICER, DISEASES OF WOMEN, STANLEY
HOSPITAL, LIVERPOOL.

THE prevalence of gonorrhoea in young and otherwise healthy married women¹ makes it peculiarly necessary not only to improve technique but to utilize all available means to make conservative gynaecological surgery a success in the presence of this infection. Until the last few years antigonococcal serum therapy has not been generally employed, although as early as 1895 de Christmas² experimented with it in guinea-pigs and rabbits. Wassermann and Wertheim confirmed his

experiments, the former showing that the poison was contained in the body of the microbe, which did not belong to a diffusible group. These results were applied by Rogers and Tory³ in 1906, and Parke Davis's antigonococcal serum was used successfully in the treatment of gonorrhoeal rheumatism. Recently Paraf⁴ pointed out the points of resemblance between the meningococcus and the gonococcus, and urged the necessity for methods of local application of the serum to bring it into immediate contact with the microbe, as is done in the treatment of cerebro-spinal meningitis by intrathecal injections. Paraf supported his views by inoculation experiments in the anterior chambers of rabbit's eyes, and by intrathecal injections into monkeys. With Nicolle's serum he cured 14 out of 16 cases of arthritis by the intra-articular injection of serum. This serum is active, possessing agglutinating, bacteriolytic, and bactericidal qualities, and is endowed with therapeutic properties against different strains of gonococci.

Encouraged by the results obtained during the war by the use of specific serums in wound infection, and more especially in gas gangrene,⁵ I determined a year ago to experiment with antigonococcal serum in the treatment of some of the cases of gonococcal infection coming under my care. I employed serum in about 30 cases, in 22 of which tubal infection was the most marked feature. Endocervicitis was present in three, and in three cases of arthritis one had occurred during pregnancy, another in the puerperium.

I adopted three methods of application. In one series I gave the serum subcutaneously diluted in normal saline, usually in a dose of 20 c.cm., repeated at intervals of a couple of days, every three days, or occasionally a week, giving in all from 20 to 200 c.cm.

In another series, on the supposition that the toxin is not diffusible, I tried the intraperitoneal method. Where there were dripping pus tubes or a pyosalpinx the tube was washed out with normal saline, after being, if necessary, opened up. Conservative surgery was adopted when possible, both tubes, or at any rate one, being left. With a syringe 20 c.cm. of serum was injected into the tubes, sometimes into the ovary, and the residue left in the pouch of Douglas. The abdomen was then closed without drainage, and the Fowler position adopted. To avert anaphylactic shock a subcutaneous or rectal saline was given simultaneously. This method, which we employed empirically during the war, has been shown by Richet⁶ to have a scientific basis—namely, that sodium chloride has a protecting action against the assaulting infection. Lumière and Cherrotier⁷ have recently shown that other sodium salts act as well.

Thirdly, in a few cases of endocervicitis with profuse leucorrhoea I tried serum packs in the vagina, alternating daily with packs moistened with equal parts of 10 per cent. salt solution and 5 per cent. carbolic acid. In one case 200 c.cm. of serum were used, but my limited supply did not permit me to utilize this method as frequently as I wished. The after-history of these local cases has been peculiarly good—one has recently become pregnant, another, who had had previous ineffective treatment extending over a couple of years, got quite well, all trace of gonococci disappearing.

In no case have I used serum intravenously, as it is the only method in which I have seen fatal anaphylactic shock supervene after the use of serum. With repeated doses there is little doubt that it is safest to use the fractional method, and not to allow more than seven or eight days to intervene between the first and second doses.

With two exceptions all these patients were married women. Thirteen had no children, and nine one only—a striking percentage of sterility. All but three were between 20 and 30 years of age.

Every effort was made to confirm the diagnosis by bacteriological findings. The history and physical signs were generally clear, and I have not included doubtful cases. The existence of purulent vaginitis and of ophthalmia neonatorum in the children was of diagnostic value. Of the 30 cases subcutaneous injections were used in 19, in 6 intratubal and peritoneal, in 3 vaginal packs, and in 2 cases of Bartholinitis, serum dressings.

RESULTS.

All the cases have made a good immediate recovery. In nearly all, either by personal investigation or through

* Read at a clinical meeting of the Liverpool Medical Institution, December 16th, 1920.

their medical advisers, I have made myself acquainted with their after-histories, which have been on the whole extremely satisfactory. There have been three definite failures—one an acute case, where an insufficient quantity of serum was perhaps responsible, and two which relapsed after a period of some months' good health, and where there was every possibility of reinfection. Further operation had to be undertaken in all three cases, otherwise the results have been good. In spite of their dislike of subcutaneous injections many of the women have said they were glad to have them, as they felt the benefit. In nearly every case relief of pain was a marked feature. Seen after varying intervals of months the patients described themselves as feeling splendid, being fit for anything, and able to do their own washing—in fact, they form a marked contrast to many other cases of gonorrhoeal infection where no serum had been given at operation, and where the presence of peritoneal adhesions causes so much pain and disability. In one case pregnancy was apparently proceeding normally. Discharges had stopped, and it was difficult to collect enough for bacteriological examinations, all of which were negative.

SPECIAL CASES.

Case 1.

A good result was obtained by the intraperitoneal use of serum in the case of Mrs. B., the mother of two children, one a girl suffering from gonorrhoeal vaginitis, while the baby had ophthalmia neonatorum. There was a left-sided pyosalpinx and an abscess in the pouch of Douglas. One tube and ovary were removed, and 20 c.cm. of serum were left in the pelvis, the abdomen being closed without drainage. There was a very slight febrile reaction the night of operation; temperature 100°, pulse 90. The patient made a good recovery. When seen eight months later she looked fit and well, and declared that she had never been in better health.

Case 2.

Mrs. V. was a case of acute salpingitis, associated with metrorrhagia. The abdomen was opened, sero-pus mopped out of the pelvis, and the tubes washed with saline solution, but not removed. Serum was administered subcutaneously in saline. There was no febrile reaction. The result was excellent, and her doctor reports that her pelvic condition ten months after operation is most satisfactory.

Case 3.

Mrs. P. was a case of arthritis of the wrist occurring about the seventh month of pregnancy (primipara). There was a profuse cervical discharge. The patient was taken into hospital and 20 c.cm. of serum were given every few days subcutaneously in saline until 150 c.cm. had been given. One injection was made into the tissues round the wrist-joint and caused a marked local reaction, with redness and swelling of the limb. This passed off, and pain ceased. The baby was born in the and was quite healthy. Both mother and baby were seen some months later in the out-patient department in excellent condition; wrist movements were normal and leucorrhoea had ceased. In this case the patient had left her husband.

Case 4.

Another favourable result was in the case of Mrs. J., where there was a history of leucorrhoea extending over two years. After the birth of a child arthritis of the left hip developed and the patient was confined to bed. She was taken into the maternity rest home for treatment, with her baby, aged 9 weeks. No gonococci were present, but her husband was also suffering from joint pains. Two subcutaneous injections of serum were given at an interval of eight days, each producing a very marked febrile reaction the same evening. The breast-fed baby also developed a serum rash. In this case the result was excellent. Pain ceased and the patient was able to leave the home in about three weeks. When seen in the out-patient department three months later she could walk well, had no pain, and was very pleased with herself.

Case 5.

In a chronic case of hydrosalpinx (Mrs. N., married six years, husband a sailor, no children) both tubes were opened up. Three doses of serum were given subcutaneously at intervals of forty-eight hours. There was a marked febrile reaction each evening, the pulse being 116 and temperature 104.6° on one occasion. This patient was seen nine months later—fornices clear, no discharge. She said she was in excellent health.

Case 6.

Another case, Mrs. T., is interesting for the light it throws on obscure causes of puerperal infection. This patient had been under treatment during pregnancy for both gonorrhoea and syphilis in the venereal disease department. Before admission to the maternity home discharge had ceased for some weeks, and the Wassermann test was negative. The confinement was normal and was conducted under the strictest

aseptic conditions, which include the shaving of the vulva and the wearing of gloves by all associated with the conduct of the labour. On the fifth day a rigor occurred, and the temperature rose to 102.8°, pulse 120. The patient was anaesthetized and thoroughly examined, the uterus being curetted and douched. It seemed so probable that the case was one of latent gonococcal infection lighting up in the puerperium that at the same time I gave 10 c.cm. antigonococcal serum with 10 c.cm. antistreptococcal serum. The latter was given not because the case was believed to be one of streptococcal infection, but as a prophylactic against a secondary infection. Temperature and pulse dropped to normal, and the patient made a good recovery. The diagnosis was confirmed by the presence of gonococci in the uterine discharge. There were no streptococci.

From such a limited number of cases I do not presume to draw any definite conclusions, but I think these favourable after-histories warrant further experiment and study. I am hoping also to receive some assistance from bacteriological and immunity experts respecting the best method of administration of the serum, with regard to the site of the injections, their incidence, and the amount to be given. On theoretical grounds it is surprising that subcutaneous injections have been so successful, bearing in mind the nature of the microbe. Can one expect to reach an organism secreting an endotoxin by the blood stream, or must some other method be found by which it can be attacked locally?

Also, what is the explanation of the vigorous febrile reaction in chronic cases where subcutaneous injections have been used, while in the acute infections, where the tubes are pouring out pus, there is practically no febrile reaction either with the subcutaneous or intraperitoneal method?

In conclusion, I should like to take this opportunity of thanking Professor Nicolle of the Pasteur Institute for his kindness in placing so much valuable serum at my disposal; to Professor Beattie and his staff for numerous bacteriological examinations; and to Dr. Ruth Nicholson and my house-surgeons and sisters for their assistance with the notes and observations.

ALBUMINURIA IN RELATION TO LIFE ASSURANCE.*

BY

F. PARKES WEBER, M.D., F.R.C.P.

In the following remarks I shall deal only with albuminuria in youth and early adult life. From the point of view of prognosis and examinations for life assurance and appointments for clerkships, etc., I prefer to divide the subject under four main headings.

I.—Albuminuria Connected with Definite Nephritis, Chronic Heart Disease, Acute Febrile Diseases, Amyloid Disease, and other Conditions, such as are met with in Hospital Wards and Ordinary Medical Practice.

These cases are well known, and in the present discussion we are not concerned with them, excepting in regard to so-called "residual albuminuria" following an attack of acute nephritis. As long as there is albuminuria of this "residual" kind a life cannot be regarded as up to the normal standard; there may still be a slumbering inflammatory process in the kidneys (one or both). Mere functional recovery in the general condition of a patient, with persistence of albuminuria, does not mean that the life is a first class one any more than does functional recovery in a case of cardiac valvular disease with the persistence of a valvular murmur and cardiac hypertrophy. The extra amount to be placed on the life should depend on a variety of circumstances—for instance, the presence or absence of tube-casts, the amount of the leakage of albumin, the results of various tests as to efficient

* Read at a discussion on the subject at the Assurance Medical Society, January 5th, 1921.

functional activity of the kidneys, the length of time that the albuminuria has lasted, the blood pressure, and the condition of the candidate in other respects.

II.—Transient Albuminuria Due to Various Causes.

Under this heading I would include cases of albuminuria due to slight temporary nephritis and renal irritation, cases connected with dietetic errors, food idiosyncrasies, or the action of drugs, and cases of transient albuminuria caused by excessive muscular work. In many cases that I would place under this heading the precise cause of the albuminuria must remain uncertain, but the important point is that the albumin disappears rapidly and completely and that the general health is and remains good. In such cases several examinations are naturally often required before the life can be regarded as a first-class one.

III.—Postural or Orthostatic Albuminuria.

Under this heading I group the cases characterized by the occasional, but not invariable, presence of albumin (sometimes little, sometimes much) in the urine passed when the patient is up (that is to say, has been up for some time) but not in that passed when he is in bed or immediately after he has been lying for some time—for instance, in that passed immediately after the night's rest on getting out of bed in the morning. The albuminous urine in these cases frequently contains an excess of "nucleo-albumin" or mucin,* and not rarely calcium oxalate crystals are found on microscopic examination, and sometimes a few red blood corpuscles. "Cylindroids" in fair numbers are frequently observed, but the presence of true tube casts, excepting a few occasional hyaline casts (found with the aid of the centrifugal machine), should be regarded as suggesting some superadded renal irritation or slight actual nephritis.† I believe that the only practical way to distinguish these cases in ordinary practice is to obtain samples of the candidate's urine passed immediately after getting out of bed in the morning. In genuine cases these samples of urine should be found to be quite free from albumin. It is an unfortunate mistake occasionally made to speak of the "morning urine" in cases of orthostatic albuminuria being free from albumin, for it is precisely the urine passed at about 10 o'clock in the morning which may be especially albuminous. For practical purposes I think that what is called "lordotic albuminuria" (L. Jehle and others) should be regarded as a variety of orthostatic albuminuria in which a decidedly lordotic position of the body acts as an essential and determining (though not the only essential) cause of the albuminuria.‡

In the discussion on the after-history of cases of albuminuria occurring in adolescents, which took place on May 2nd, 1911, at the Medical Section of the Royal Society of Medicine, I made some remarks on the favourable prognosis in such cases,§ and said that I did "not think that albuminuria occurring in apparently healthy adolescents could justly be regarded as belonging to any other class than orthostatic albuminuria, unless it could be definitely ascertained that the urine passed immediately on getting out of bed after the night's rest contained albumin." If anything, I am now still more convinced that in uncomplicated cases of orthostatic albuminuria the life may be regarded as a normal one from the life assurance point of view. Moreover, no young person should be prevented from living an ordinary active life merely because of the presence of orthostatic albuminuria. Indeed, for these cases an active life—as much as possible in the open air, without over fatigue—is probably the best. True orthostatic albuminuria may occasionally be met with up to 25 to 30 years of age (and possibly even later in life). In some way or other it is often connected with the tall

"lanky" build of body suggestive of visceroptosis; it has been much written about, especially by Continental authors, and, as every doctor now knows, is frequently associated with, and excited by lordosis (Jehle). There is nothing surprising in the fact that it may occasionally exist in association with true nephritis (for instance, after scarlatina), and that it may be met with in the subjects of tuberculosis, syphilis, etc. The few *post-mortem* examinations that have been recorded tell us nothing more than this. It seems, indeed, quite natural that, occurring, as orthostatic albuminuria not rarely does, in "overgrown" children and in tall, flat-chested and often lordotic adolescents, it should be occasionally associated with early pulmonary tuberculosis. I have observed orthostatic albuminuria in two young men with grave forms of congenital heart disease. Dr. Mackenzie Wallis has kindly informed me that in the albuminuric case to which he referred—a man in whom albuminuria was present for thirteen years without apparently harming him until at last he died at the age of 30 years from uraemia—the albuminuria was not of the orthostatic type, and was almost certainly due to a true chronic nephritis.‡

In regard to prognosis (and life assurance) in cases of adolescent albuminuria help can doubtless be obtained from a chemical examination by estimating the relative proportions of serum-albumin and globulin in the urine,§ but it is of at least as great importance to ascertain whether the albuminuria conforms to the orthostatic type—whether albumin is altogether absent from the urine passed immediately on getting out of bed in the morning—though this latter investigation may give rise to considerable inconvenience if the examinee cannot be trusted.

IV.—The Presence of Albumin (frequently only a trace) accompanying Minute Quantities of Pus, Blood, or Semen in the Urine.

The slight opacity in the urine due to the presence of minute quantities of pus or blood, or pus and blood, in the urine may easily be overlooked, or wrongly neglected as of no importance, in examinations for life assurance or appointments such as clerkships, etc. (Naturally in the case of females a difficulty is more likely to arise owing to admixture of the urine with vaginal or slight leucorrhoeal discharge.) The haze which calls for a microscopic examination may be not more than that due to the presence of bacteria in urine from cases of bacteriuria or in urine which is decomposing. I do not know how it compares with the opalescence which, according to Mackenzie Wallis, may exceptionally be observed in urines containing an excess of eglobulin.¶ Whenever it is evident by the ordinary tests that an opacity (however slight) in the urine is not due to phosphates (or, after cooling, to urates), a

* F. P. Weber, Congenital Heart Disease, with Extreme Secondary Polycythæmia and Orthostatic Albuminuria, *Lüdingburg Medical Journal*, 1903, New Series, vol. ii, p. 18; F. P. Weber and G. Dörner, Congenital Pulmonary Stenosis, *Proceedings of the Royal Society of Medicine, Clinical Section*, London, 1911, vol. iv, p. 85. In connexion with these two cases I find that F. Eigenberger (*Zentralblatt für innere Medizin*, Leipzig, 1920, vol. xli, p. 334) refers to the case of a young man with polycythæmia rubra (secondary to cardiac disease, if I rightly understand the author) in whom the presence of orthostatic (lordotic) albuminuria was discovered: a lordotic position of his body caused his urine to contain albumin, a little blood, and abundant cylindroids.

† Dr. Mackenzie Wallis tells me that though there was well marked albuminuria in this case, the patient was observed to have puffiness about the eyes in the early mornings; his brachial systolic blood pressure was constantly 160 mm. Hg. and red blood cells (though no tube casts) were found in the urinary deposit. The case has been described in full by Dr. Ivor J. Davies, *Lancet*, 1920, ii, p. 1249.

‡ Cf. R. L. Mackenzie Wallis, Non-nephritic Albuminuria, *Proceedings of the Royal Society of Medicine, Section of Medicine*, 1920, vol. xiii, pp. 55-104.

§ Mackenzie Wallis (loc. cit. p. 100) writes: "In my opinion eglobulin is really globulin which has associated with it a small quantity of lipoids. In this respect eglobulin is identical with the leucithin-globulin isolated from pseudo-chylous (fusant) effusions, the degree of opalescence depending on the amount of associated lipoids. This eglobulin is precipitated by acetic acid in the cold, and, in my opinion, the protein present in the urine which gives this test. An excess of this eglobulin containing excess of lipoids either in the blood, pleural, pericardial, or peritoneal effusions, or in the urine, gives rise to a marked opalescence, and when this globulin is removed the opalescence disappears." Mackenzie Wallis quotes a case described by Braun† and Pezon (1892), in which actually the urine spontaneously deposited rhombic crystals of globulin. In regard to pseudo-chylous effusions cf. also Mackenzie Wallis and Schöbinger, *Quarterly Journal of Medicine*, Oxford, 1910, vol. iii, p. 701; Mackenzie Wallis, *Proceedings of the Royal Society of Medicine, Medical Section*, 1913, vol. vi, p. 135; and H. A. Lediard, *Ibid.*, p. 123.

* A trace of nucleo-albumin in the urine passed immediately on getting out of bed in the morning must not be mistaken for albumin. In the brachial systolic blood pressure in these cases is in general, I think, slightly below rather than above the average.

† The voluntary assumption of a lordotic position of the body (artificial lordosis) is sufficient in some subjects to induce temporary albuminuria, the view that in cases of "orthostatic albuminuria" ordinary muscular exercise of walking position of the body, which induces the albuminuria in the urine when the affected individual gets up after a night's rest.

‡ Cf. also F. P. Weber, Remarks on Orthostatic Albuminuria, *Proceedings of the Royal Society of Medicine, Medical Section*, 1911, vol. iv, pp. 125-33. In this paper I referred to individual cases I had met with.

microscopical examination (even a hasty one, without waiting for a sediment to form and without the help of the centrifugal machine) may prove of extreme value. At examinations for appointments and life assurance the discovery of minute quantities of blood, not sufficient to produce any reddish coloration of the urine, may lead to the detection of renal tuberculosis, as in the case of a young man whom I recently examined for a clerkship. In such cases the correct diagnosis must of course be confirmed by special examinations, such as by cystoscopy and by catheterizing the ureters, to see if only one kidney is affected. On repeated examinations in cases of this class the urine may sometimes be found apparently free from albumin (by the ordinary boiling and acidifying test), though its slight opacity when freshly passed should lead to a microscopical examination being made. On rare occasions, in such cases, even the slight obvious opacity may temporarily be absent from urine, which by microscopical examination of the centrifuge sediment is found to contain minute quantities of blood or pus.

I understand from Dr. Lister (though I have not observed it myself) that the urine at the commencement of an attack of gonorrhoea (congestive stage) may sometimes contain a little albumin even before the appearance of any purulent discharge.

After the subsidence of an attack of haematuria of uncertain causation the presence of a little pus in the urine by microscopical examination may indicate grave disease, such as a malignant tumour involving the pelvis of one kidney.* This whole subject, however, I need not further discuss here.

ON THE ACTION OF CERTAIN SPECIAL PREPARATIONS ON MALARIAL PARASITES AND THEIR EMPLOYMENT IN THE TREATMENT OF MALARIA.

BY

MAJOR J. PRATT-JOHNSON, M.C.,
D.A.D.M.S. (PATHOLOGY),

MAJOR KENNETH GILCHRIST, M.C.,

AND

CAPTAIN HAY-MICHEL, S.A.M.C.

THESE investigations were carried out at No. 4 General Hospital, S.A.M.C., Roberts Heights, during 1917-19 on malarial patients invalided from the German East African campaign. The majority of the cases were of a severe type, associated with marked anaemia and debility, numerous relapses occurring in hospital while under quinine treatment (25 to 30 grains daily). Of 8,788 hospital cases 61 per cent. showed benign tertian parasites in their peripheral blood, 23 per cent. malignant subtertian, 16 per cent. both benign tertian and malignant subtertian parasites. The average period in hospital and convalescent camp of these cases was fifty-one days, during which time the blood was examined at weekly intervals and the patients kept on routine daily quinine treatment. Parasitological relapses occurred during this period of observation in 24 per cent. of the benign tertian cases, 11 per cent. of the malignant subtertian cases, and 39 per cent. of the mixed infections. The circumstances under which these cases contracted malaria (a particularly strenuous military campaign in the tropics) suggested a special terminology to meet this resistant clinical condition—namely, "campaign malaria," which apparently owes its intractability to repeated reinfection associated with severe physical strain in unacclimatized individuals only partially protected from a tropical climate and frequently insufficiently supplied with suitable food.

The frequency with which relapses occurred and the slowness with which these patients recovered a condition of good health emphasized the importance of testing any

remedy which might cut short the period of treatment necessary and reduce the number of relapses. Accordingly these investigations were initiated, with the object of providing if possible a more effective treatment. It is not proposed to deal in this paper with the comparative studies made of the results of treatment of different infections with varying doses of quinine administered by the oral, intramuscular, and intravenous routes. The practical outcome of this work, however, was the adoption of a standard treatment for all average cases of malaria. This treatment consisted of 30 grains of quinine in solution by the mouth daily for three weeks, followed by 20 grains daily for one month and subsequently 10 grains daily for two months.

NEO-SALVARSAN, SALVARSAN, NEO KHARSIVAN, KHARSIVAN, GALYL.

In view of the debilitated condition of many of the cases selected for treatment it was necessary to exercise the greatest care in the employment of these toxic preparations. Accordingly the patients were specially prepared, and the dose of the "606" preparations employed was invariably about half that dose commonly used for the treatment of syphilis (neo-kharsivan, neo-salvarsan, 0.45 gram; salvarsan, kharsivan 0.3 gram; galyl 0.2 gram).

Until some experience of these preparations had been obtained in malarial patients it was customary at first to give intravenous injections at weekly intervals. Subsequently, however, it was found that intravenous injections could with safety be given on alternate days for three or four injections, and in one of the cases reported in this series fourteen intravenous injections of 0.2 gram galyl were administered during an inclusive period of twenty-two days, as many as five injections being given on successive days without any obvious harmful effects.

During the past three years some thousands of intravenous injections of these preparations have been administered in malarial subjects without a single fatality. It is therefore clear that the employment of intravenous injections of the above preparations in malarial subjects is not attended by any appreciable or special risk, provided the doses and methods recommended are used and the precautions enumerated are fully observed.

Apart from the general contraindications in regard to the employment of these preparations commonly recognized when considering the treatment of syphilis, it is necessary specially to consider the following points in regard to the employment of these preparations in malarial subjects.

(a) *Tachycardia and Dilatation.*—These are symptoms of the disease resulting from anaemia and toxæmia. They improved, however, rapidly as a result of intravenous injections of salvarsan and galyl, and in 154 cases subjected to this treatment, the majority of whom had some cardiac embarrassment, not a moment's anxiety on this score was experienced.

(b) *Pyrexia.*—Some observers have held that following an injection of "606" or galyl the temperature often rises 1 to 1.5 degrees, sometimes accompanied with slight rigor, nausea, and vomiting as part of the general reaction to the drug. In a series of over 790 injections these phenomena were observed only seven times with the above doses.

(c) *Renal Complications.*—As these drugs are toxic, it is necessary for the patients' safety that they should be eliminated fairly rapidly. Where, therefore, there is a history of recent nephritis, or where the symptoms of such a condition are present (albumin, oedema, etc.) an injection should not be given.

(d) *Gastro-intestinal Conditions.*—As vomiting is also a fairly frequent symptom of reaction after injection, severe vomiting, diarrhoea, or obstinate constipation should be corrected before an injection is given.

Preparation of the Patient.

Sufferers from malaria should have complete rest in bed for at least twenty-four hours before an injection. Their diet should be light and easily digested during this period. The bowels should be opened either by a purgative pill (for example, pil. hydrarg. coloc. co. with hyosc.) the previous night, followed by saline (mist. alba) the following morning or by an enema in the morning before injection. A light breakfast—one egg, two slices of toast, and one cup of tea—given at least four hours before injection, may be allowed, but no food should be

* In one such case, a man, aged 33 years, under my observation in 1918, the patient (owing to some mistake) was forced to join the army, but was soon transferred to a military hospital and then set free. He died in March, 1920, and the post-mortem examination showed a malignant tumour and pyonephrosis of the left kidney, with secondary tumours elsewhere in the body. This was Case 11 in a paper which I published (in regard to another subject) in the *International Clinics*, Philadelphia, 1920, series 30, vol. iii, pp. 43-51.

given again till four hours after the injection, when a cup of tea with a slice or two of bread-and-butter may be taken. A complete meal should not be allowed until next day. A sample of urine of the preceding twenty-four hours should be tested on the morning before injection, and if this is found to contain albumin or sugar the injection should not be given.

Considering the small doses that are advocated in these cases the above precautions may seem excessive, but in view of the great debility of these patients and the frequency of dosage advocated, it is important to carry out such preparatory measures if untoward incidents are to be avoided.

Reactions.

Some of the reactions have been alluded to. With such small doses, 0.2 or 0.3 gram, anything approaching a marked reaction has not been seen. A few cases complained of congestive headache. In 650 injections of galyol, only on one occasion was an actual rigor observed to follow an injection, and as in this case a tertian paroxysm was expected on this day, it was in all probability quite unconnected with the injection. Vomiting was observed in one case in which 0.5 gram salvarsan had been given.

Results.

The total number of patients treated for purposes of investigation was 154. The clinical action of "606" preparations may be considered under the following headings:

1. *Nervous*.—Headache frequently disappeared not to return even with subsequent rigors.

2. *Pyrexia*.—Where rigor and pyrexia followed an injection at the usual period of the vegetative cycle of the parasite they were invariably milder in degree, and frequently aborted—in fact, experience has shown that these drugs are of considerable diagnostic value in differentiating the two main types, benign and malignant, the former being almost invariably aborted.

3. *Tonic Effect*.—Generally speaking, the tonic effect of "606" preparations is well marked, and rapidly becomes apparent; anorexia, lassitude, and debility soon give way to a feeling of well-being, while tachycardia and shortness of breath, consequent upon anaemia and cardiac dilatation, rapidly improve.

4. *Spleen*.—Spleenic enlargements under the influence of these drugs disappear with remarkable rapidity.

5. *Liver*.—In cases where enlargement of the liver was marked with icterus of skin and conjunctivae, rapid improvement has generally followed a single injection, bilious vomiting, furred tongue, and foul breath clearing up within a short period.

6. *Lungs*.—A number of men with malaria were admitted suffering from a dry bronchitis with severe cough. It was noted that rapid improvement followed an injection, though the same frequently occurred after a few doses of quinine had been taken.

Action of "606" Preparations on Malarial Parasites.

1. *Benign Tertian Malaria*.—As a result of numerous observations on the blood after intravenous injections with the above preparations in the doses advocated, without any other medicinal treatment, it was definitely determined that "606" preparations exert a marked parasitocidal action on the benign tertian parasite. Thick blood smears showing numerous parasites commonly become negative within twenty-four to thirty-six hours. No appreciable difference was observed in these different "606" preparations, the result of treatment being closely similar in each case. The action of these preparations is closely analogous to the action of quinine, although "606" preparations appear to be more active and to produce much more rapid effects, especially in chronic resistant infections associated with enlarged spleen and marked anaemia.

2. *Malignant Subtertian Malaria*.—The action of "606" preparations on tropical malaria exhibits a very marked difference from their action on benign tertian malaria. Observations showed that "606" preparations have no definite parasitocidal action on any stage of the malignant subtertian parasite. When employed, however, in association with quinine, these preparations appear to render the parasites more vulnerable to the action of quinine, the

infection being controlled and cured with smaller doses of quinine than would be required without these preparations. The employment of "606" preparations in malignant subtertian malaria appears to be specially indicated in resistant infections with marked anaemia and cachexia, owing to their action in breaking down resistance to quinine and their tonic effects.

Relapses.

The selective action of "606" preparations for benign tertian infections is very marked. In spite of this, relapses are common even when this preparation is combined with quinine treatment. Total eradication is doubtless possible with "606" preparations alone in early simple infections, but the majority of the cases treated were chronic cases resistant to treatment, of which a considerable number relapsed even while under treatment in hospital. Relapses, however, are much less frequent when several injections are given on alternate days in addition to quinine treatment.

It is not possible with "606" preparations alone to effect Ehrlich's *therapia magna sterilisans* except in the earliest infections. Freedom from relapses and total eradication of the infection cannot therefore be promised after treatment with numerous intravenous injections of "606" preparations.

In malignant subtertian malaria quinine must be employed in addition, as "606" preparations have little direct destructive action on the parasites. When these preparations are used in addition to quinine the action of the latter is intensified, and the progress towards recovery is much more rapid.

Detection of Parasites.

The thick smear was always employed in searching for parasites in the peripheral blood; it is a rapid and efficient method of controlling the results of treatment. It is possible to demonstrate parasites easily by this method when it may be impossible to find them on examination of thin films even after a prolonged search. Using this method it was found that in 4,043 cases of malaria admitted into hospital with positive thick smears, 23 per cent. showed parasites persisting in the blood on the eighth day of treatment with an average daily dose of quinine of 23 grains. The average persistence of parasites in thick smears in these cases was nineteen days. This fact indicates the severe nature of the cases and demonstrates the slow action of quinine in reducing heavy infections in markedly debilitated individuals. Resistant benign tertian infections responded readily to "606" given intravenously together with quinine by the mouth owing to the parasitocidal action of "606" on the benign tertian parasites. Intramuscular injections of soamin and quinine orally offered no advantage over quinine and inorganic arsenic in these resistant cases, as the following statistics indicate:

Results of re-examination of blood, after an average interval of eight days, in cases of benign tertian malaria, positive on first examination—34 cases treated with quinine and an average of one injection of "606"—compared with 3,171 cases treated with quinine only, and 44 cases treated with quinine and an average of two injections of soamin. In the 44 cases treated with quinine and soamin the blood was re-examined after an average interval of 6.5 days.

	Quinine + 606.	Quinine.	Quinine and Soamin.
Number of cases positive on first blood examination	34	3,171	41
Number positive on re-examination ...	Nil	710	10
Percentage of cases positive on re-examination	Nil	22	22.7
Averagedaily quinine (grains) in interval before re-examination	11.5	23.2	23.6
Average persistence of asexual forms in cases positive on re-examination	Nil	19	19.2

Mixed Infections.

The failure of treatment with "606" preparations alone to prevent relapses in mixed infections, even when the treatment is pushed, is shown by the following cases:

Case 1.—Mixed infection (benign tertian and malignant tertian). Intravenous injections of 0.20 gram galyol on the 1st, 2nd, 3rd, 4th, 6th, 7th, and 8th days. Parasite relapse of

malignant rings on the 16th day, and benign tertian parasites together with malignant rings on the 24th day. A few crescents were also found on the 21st day. No other treatment given.

Case 2.—Mixed infection (benign tertian and malignant tertian). Intravenous injection of galyl 0.30 gram on the 1st day. Parasite relapse of benign tertian on the 12th day. Further injections of galyl 0.20 gram on the 17th, 19th, 21st, 23rd, 25th, 29th, 31st, and 33rd days. Parasite relapse on the 39th day of benign tertian parasites. Crescents were daily found in the blood from the 21st to the 39th day. No treatment other than galyl given during the period of observation.

Case 3.—Mixed infection (benign tertian and malignant tertian). Intravenous injections of galyl 0.20 gram on the 1st, 2nd, 3rd, 5th, 6th, 7th, 9th, 14th, 16th, and 9th days. Parasite relapse on the 20th day, benign tertian parasites and numerous malignant rings. Crescents found daily from the 5th to the 15th days, and not found from the 16th to the 23rd days. Treatment, galyl only.

Case 4.—Mixed infection. Intravenous injections of galyl 0.20 gram on the 1st, 2nd, 3rd, 4th, 6th, 7th, 8th, 14th, 15th, 16th, 17th, 18th, 20th, and 22nd days. Parasite relapse with numerous malignant rings on the 14th day to the 23rd day. On the 24th day benign tertian parasites were also found. Crescents were found almost daily. Treatment, galyl only.

SOAMIN.

Numerous intramuscular injections of soamin were administered in severe resistant cases of various types of malaria. Soamin exhibits no parasitocidal action on the parasites of either benign tertian or malignant subtertian malaria. Its beneficial action is confined to the breaking down of the resistance of parasites to quinine.

TARTAR EMETIC IN "CRESCENT INFECTIONS."

A small series of twenty-seven cases of malignant subtertian malaria with crescents in finger blood were treated by tartar emetic injections, the total number of injections administered being 137.

No demonstrable effect attributable to the injections was observed on crescents. Even repeated doses of 20 cg. of tartar emetic did not appear to produce breaking down of the crescents in the blood.

No advantage as to the rapidity of elimination of crescents from the blood could be demonstrated between a group of cases treated by quinine only and a group of cases treated by quinine together with an average of five injections of tartar emetic. The most rapid and certain method of eradicating crescents from the finger blood is to treat the patient thoroughly with quinine (30 grains daily). Under such treatment crescents disappear in an average of fifteen days. Supplementary treatment with arsenic and iron is indicated, and in unusually resistant cases intravenous injections with "606" preparations, or intramuscular injections of soamin, are advisable to break down the resistance to the action of quinine, of the "ring" forms from which the crescents arise.

In regard to the prevention of relapses, these have occurred in both benign tertian, malignant subtertian, and mixed infections after treatment with an average of four to six injections of tartar emetic in each infection. Tartar emetic has no demonstrable effect on the asexual forms of the parasites of either benign tertian or malignant subtertian infections, and exerts no influence on the clinical course of the disease.

MERCURY AND ANTIMONY OINTMENT.

A small series of eleven cases were treated with quinine and inunctions with an ointment composed of antimony 2 parts, mercury 30 parts, lanoline 68 parts. About 1 drachm was rubbed in daily for fifteen minutes. Inunctions were continued for an average of twenty-five days. The inunctions did not appear to have any direct action on the parasites or to intensify the action of the quinine which was administered at the same time. No therapeutic effects were observed.

CONCLUSIONS.

1. Neo-salvarsan, salvarsan, neo-kharsivan, kharsivan, galyl, administered intravenously, may be employed with safety in the treatment of all forms of malaria, provided the doses and methods recommended herein and the precautions enumerated are fully observed.
2. These preparations, in the doses recommended, exert a marked parasitocidal action on the benign tertian

parasite, thick blood smears usually becoming negative to thirty-six hours.

3. These preparations have no definite parasitocidal action on any stage of the malignant subtertian parasite. When used in addition to quinine, the action of the latter is intensified and the progress towards recovery is much more rapid.

4. Generally speaking, the tonic effect of these preparations is well marked in all cases of malaria; anorexia, lassitude, and debility soon give way to a feeling of well-being, while tachycardia and shortness of breath, consequent upon anaemia and cardiac dilatation, rapidly improve. Splenic enlargements disappear with remarkable rapidity.

5. The employment of these preparations is recommended, in addition to quinine treatment, in chronic resistant infections and malarial cachexia. Three or four injections at weekly intervals are recommended. Freedom from relapses cannot be promised even after numerous intravenous injections. In regard to the preparation of the solutions and technique of administration, the usual methods are followed in each case.

6. Soamin exhibits no parasitocidal action on the parasites of either benign tertian or malignant subtertian malaria. Its beneficial action is confined to the breaking down of the resistance of chronic infections to quinine.

7. Tartar emetic has no demonstrable effect on the sexual or asexual forms of the parasites of either benign tertian or malignant subtertian malaria, and exerts no influence on the clinical course of the disease. The most rapid and certain method of eradicating crescents from the finger blood is adequate quinine treatment (30 grains daily) and arsenic.

8. Inunctions of mercury and antimony ointment do not appear to exert any therapeutic action in malaria.

This paper is included in a report on "Malarial Research in South Africa during the War," to the Minister of Defence, Union of South Africa.

MEDICAL, SURGICAL, OBSTETRICAL.

SPASMODIC HICCOUGH.

In view of the recently reported plague of hiccough in Montreal and Paris an account of two cases which have recently come under my care, and are, so far as I am aware, the first cases to be noted in England, may be of interest to your readers.

Case 1.—A man residing near high downland, accustomed to easy open-air life, who had not recently been away from the district, presented as the initial symptoms frontal headache and slight rise of temperature. On the second day a cough developed, and the hiccough first began at the end of a fit of coughing and lasted an hour. In an hour's time another attack occurred, lasting an hour and a half. These recurrent attacks continued for two days. On several occasions the hiccough continued until retching was set up, and, although no material was vomited, the act of retching appeared to stop the hiccough for a time. It was noted that the hiccough was more violently spasmodic than is usual in an ordinary mild persistent attack. The temperature throughout remained at 101° F., and finally dropped by crisis. The frontal headache continued and heavy night sweats occurred. After trying all the usual homely remedies my advice was sought at the end of the first day, and a mixture containing potassium citrate, bismuth subnitrate, tincture of belladonna, and dilute hydrocyanic acid was given every four hours. Very little relief was obtained, and the attack finally yielded at the close of the second day to a mixture of sodium, potassium and ammonium bromide, leaving the patient weak and shaken.

Case 2.—A young man employed in business near the docks. The symptoms differed from those in the previous case in that a smart attack of diarrhoea occurred coincidently with the onset

of the hiccough. Frontal headache and temperature as in Case 1. No night sweats. The attack did not yield to bromides, and only subsided when benzyl benzoate was given, duration thirty six hours.

Clifton, Bristol.

FATAL POISONING FROM INHALATION OF ACID FUMES IN A LABORATORY.

An engineering student was engaged on December 8th, 1920, in dissolving various metallic substances in mineral acids. The exercises for the day consisted in the identification of pyrolusite (MnO_2), stibnite (Sb_2S_3), and bauxite ($Al_2O_3 + Fe_2O_3$). The mineral acid which was advised for employment was hydrochloric acid, but according to the patient's own statement he made use instead of sulphuric acid.

He placed a vessel containing this acid and one of the metals in an ordinary fume chamber, and on going to remove it about an hour later he inadvertently bent too much into the chamber and inhaled the fumes. He felt, for the moment, sick and dizzy, but experienced no further ill effects till the middle of the following night, when he began to suffer from severe and rapidly increasing dyspnoea. Next day, December 9th, he was seen by Sir Robert Woods, who found him suffering from very severe oedema of the larynx and pharyngeal tissues. Scarification and other treatment was adopted, with the result that the oedema rapidly subsided, but as his general symptoms pointed to severe illness, he came under my care on December 12th.

On this date he looked anxious and ill, there was a slight icteric tinge in the sclerotics, the tongue was furred, the throat still showed traces of the recent severe inflammation, the heart sounds were normal but weak, the pulse was feeble (120 to the minute), and the respirations were rapid. Mild diffuse bronchitis existed, with crepitations, and a pleural rub at the base of the left lung, the abdomen appeared normal. The urine was scanty, highly albuminous, with a faint biliary reaction. The temperature on this date was $103^\circ F$. Treatment by alkalis, glucose, oxygen inhalations, etc., was ordered, and the next morning the patient was somewhat better, and was bringing up freely a lemon yellow coloured expectoration. The improvement persisted for a couple of days, but was then followed by rapidly increasing weakness and loss of weight, and finally a lethal termination on December 19th, just ten days after the initial misadventure. During the last few days the liver became much enlarged, there was persistent diarrhoea of a thin watery character, fall of temperature to subnormal, extreme and rapid emaciation, cyanosis and rapid breathing, without increase of pulmonary signs.

The inability to state exactly what fumes were the cause of the trouble diminishes the value of this report, but it is nevertheless placed on record owing to its obvious importance to laboratory workers. The professor in charge of the laboratory informs me that the same routine of work has been carried out by classes for years, and that he has never before heard of even trifling malaise. The delay in the development of the symptoms is also worthy of note.

Dublin.

T. GILLMAN MOOREHEAD, M.D.

PATENT DUCTUS ARTERIOSUS.

In your issue of December 25th, 1920, I have read the very interesting account by Dr. Carey Coombs of his four cases of patent ductus arteriosus. In the *Archives of the Middlesex Hospital*, vol. xvi, No. 13, December, 1913, I reported three cases, all proved by autopsy, of patent ductus arteriosus, with no other lesion present, but all in children under one month old. In all these cases no murmur of any description was heard, and the attacks of cyanosis—varying in length, but completely passing off for longish intervals—were the marked feature of these cases. Whilst serving in the army in Malta I was asked by Sir Archibald Garrod to see a baby with a view to performing tracheotomy, but it was finally decided against, and at the autopsy a patent ductus arteriosus was found. No bruit was present in this case, but cyanosis and dyspnoea were the marked features.

Evidently from Dr. Coombs's observations a bruit develops if the individual lives to adult age, and endocarditis is added to the already patent ductus arteriosus. Without the endocarditis I feel sure no bruits of any character are present.

Reports of Societies.

ALBUMINURIA IN RELATION TO LIFE ASSURANCE.

At the meeting of the Assurance Medical Society on January 6th a discussion on "Albuminuria in relation to life assurance, especially in adolescents," which had been adjourned from the meeting of November 3rd, 1920 was resumed by Dr. F. PARKES WEBER, whose paper appears on page 78. The President of the Society (Dr. L. D. LISTER) was in the chair.

Sir JAMES GALLOWAY related his experience with some cases of orthostatic or, as it might perhaps be called, latent albuminuria. In the early days of the war when much difficulty arose from what was called "trench nephritis," he had a conversation at the front with Sir Wilmot Herringham. The scare about trench nephritis had caused a great many examinations to be made, and a certain number of men were found to have albuminuria, which was not surprising in view of the campaigning conditions. But experience showed that a large number of cases with albuminuria which it had been supposed might lead to troublesome results were of this harmless type, and a more extended investigation later on, when the casualty clearing system had further developed, made it possible to define such cases. After a short rest and a period during which they were under careful scrutiny some of these men were passed again for service, and were kept right, at all events for the period of the war. He would not say that even in these cases there was no subsequent trouble, for he did not quite agree with Dr. Parkes Weber as to the total harmlessness of the condition. But the number of men suffering from this orthostatic albuminuria was very much larger than might have been concluded from the experience of civil practice. Great care was necessary in arriving at a diagnosis in such cases. If the question of syphilitic infection were raised, as occasionally happened in such cases, grotesque errors in diagnosis might be made, leading to the use of drugs such as salvarsan in the excitement of the occasion—not a very prudent plan of treatment. The speaker had thoroughly tested such cases, examining the urine before and after exertion. One form of exertion was to walk round the Outer Circle of Regents Park in a given time, and it was found that after this exercise the albumin was increased in quantity, although on rising in the morning it had been absent or negligible. Another case which came under his care was that of a pensioned soldier who had been discharged on account of nephritis. Albuminuria had been found early in his war service, and he had been sent home, and after a rest sent out again, but finally discharged. This man, who was of the lanky, flat-chested type, was evidently one of the orthostatic cases, and was now practically albumin free. But the previous diagnosis and treatment had had the effect of giving him a nervous disinclination for much work. Nevertheless, a man of this type, quite apart from his physique or his neurasthenia, was not to be regarded as a first class life, because the functions of the kidney could not be considered as properly performed.

Dr. H. BATTY SHAW said that it seemed to him they could not avoid accepting the position that pre renal albuminurias or proteinurias were due to nephrotoxic substances brought to the kidney by the blood stream, and not generated in the kidney *ab initio*. If this was so obvious an explanation of cases of proteinuria accompanied by coarse changes in the kidney, was it not probable that the intermittent temporary or occasional proteinuria of adolescents, or of persons of any age, was also due to the operation, in a large majority of cases, of foci of infection at a pre renal site? These, while incapable of producing fever with its associated manifestations, were capable on occasion of producing temporary disorder of function in the renal parenchyma with consequent albuminuria. That orthostatic proteinuria existed had been accepted too readily as proof that the proteinuria, at any rate of adolescents, was mechanical in its origin. Foci of inflammation at any pre renal site were quite capable of causing proteinuria, whether temporary or for all time, slight or severe, and it was safe to assume that the foci of infection which only produced proteinuria in young

persons on assuming the erect posture need be no bar to insurance. Dr. Shaw detailed a series of observations which went to show that proteinuria might be constantly present although the percentage of damaged glomeruli of the kidney was very low, and might be only occasionally present in other cases in which the percentage of damaged glomeruli was large; his conclusion was that the degree of proteinuria was not proportional to the number of damaged glomeruli, and must be assumed to depend rather upon some agency present in the blood which was capable of altering the glomerular elements sufficiently to allow proteinuria to occur, without, however, altering them structurally. Dr. Batty Shaw's practical suggestions were as follows:

Cases of adolescent proteinuria—that is, in persons under 30—showing no other abnormality than proteinuria, which was absent when the urine was examined after a night's rest, should be accepted at ordinary rates. If the proposer showed proteinuria after a night's rest, his insurance should be postponed, or he should be given a short endowment with a load.

If the adolescent proposer showed proteinuria and hyperpiesis after a night's rest he should be rejected.

If a proposer over 30 years of age showed nothing else but proteinuria, which disappeared after a night's rest, he should be accepted, but with a load; if the proteinuria persisted after a night's rest he should be postponed; and if proteinuria persisted and was accompanied by hyperpiesis, and the latter was not abolished by a night's rest, he should be rejected.

Dr. H. W. COLLIER mentioned the case of a man, 56 years of age, who had lived an exceedingly active life, and was of good family and personal history, who proposed himself for assurance. Thirty years previously he was declined on account of albuminuria, but two years afterwards was accepted by another company at ordinary rates, the medical examiner, apparently, finding no albumin. The man himself knew, however, that throughout his life, whenever his urine had been tested, albumin had been found save on that one occasion. The speaker recommended his acceptance, but with the addition of five years to the age, and this the man declined, as he considered himself in every way a first-class life.

Dr. H. M. ABEL thought the calcium lactate method of testing likely to be of much use, but it was a treatment, and would usually involve giving doses—and not small doses either—to another doctor's patient. Would it not be good for the office, the proposer, and the doctors, if an arrangement could be made whereby, in special cases only, the examiner could get into touch with the doctor in charge of the case? On the general question, he was of opinion that any given case which was proved to be adolescent postural simple albuminuria, with all other conditions favourable, should be accepted at ordinary rates.

Dr. F. G. CHANDLER mentioned that one of the largest organizations in this country, employing great numbers of boys, who were retained in its service for the rest of their lives, subjected the boys to careful medical examination, and kept a complete record of their sick leaves. Not a few of the boys had albuminuria; at one time such boys were rejected, but for twenty-five years now they had been accepted, and the record of health of these boys was in every respect as good as that of the others. The albuminuria in some cases had persisted up to manhood. It was proved, therefore, that there existed an albuminuria which was not pathological. The speaker maintained that—provided there was no abnormality in the appearance of the person, his past history, and the state of the cardio-vascular system, also in certain urine tests such as for casts and the type of protein—they were justified in passing the proposer as a first-class life even though he had a trace of albumin.

Dr. WITHERS GREEN protested against the use of the terms "orthostatic" and "adolescent," and suggested in their place "functional," "physiological," and "perambulatory." The word "orthostatic" was meaningless now, and would be a difficulty for those who came after.

Dr. HINGSTON FOX, who had opened the subject at the first meeting, said that one thing which had been gained by the discussion was the fuller recognition of the fact that a favourable and harmless type of albuminuria really existed independently of disease of the kidney. He was sorry Sir James Galloway should have repeated the old heresy that in such cases the kidneys could not be quite sound. He did not exclude the phenomenon of septic absorption, as suggested by Dr. Batty Shaw, but in many

of the cases he had seen, when the persons concerned were in robust health with good digestions and capable of much exertion, it was difficult to believe that the passage of a little albumin was due to any septic absorption; it was much more probably due to certain functional states of the blood circulation. He saw nothing better in the way of a name than the "albuminuria of adolescence." It implied no theory and begged no question as to physiological or functional disturbance. What were the causes which interfered with the normal defensive action of the kidney cells in keeping albumin out of the urine? It seemed to him very reasonable that the conditions of blood pressure and of the blood itself in respect to its coagulating power and thinness would be likely to interfere with that defensive property; and Sir Douglas Powell's reminder at the last meeting that the very structure and purpose of the glomeruli was to produce a retardation of current for the functional purposes of the kidney was rather illuminating from that point of view, because if that blood secretion were too much retarded, surely the cells could no longer work as they ought to do.

A CASE OF PLAGUE IN DUBLIN.

At a meeting of the Medical Section of the Royal Academy of Medicine in Ireland, held on December 10th, 1920, Dr. H. DRURY and Sir ARTHUR BALL reported a case of bubonic plague which had occurred in Dublin.

The woman, aged 25, was seen by Sir Arthur Ball, who found a gland in the groin the size of a walnut, with a history of intense local pain of three days' duration. On admission her temperature was 104°. The skin over the gland was not inflamed. The patient was covered with flea-bites. The excised gland was examined by Dr. Sygne, who found that it contained large numbers of plague bacilli.

When Dr. Drury first saw the case, on the third morning after operation, he was struck with her typhus-like aspect. The patient's temperature was then 102°, her pulse-rate 100 but very weak, her respirations 22. Except for a deep and exquisitely tender swelling, 2½ in. by 1 in. immediately above and parallel to Poupart's ligament, the abdomen was normal. There was no vesicle or pustule to indicate the site of inoculation. On the sixth day of the disease the temperature began to fall steadily, rising again on the eleventh day to 102°, and becoming definitely normal on the thirteenth day. The swelling above Poupart's ligament gradually subsided.

Dr. BIGGER, in describing the precautions taken by the authorities to prevent extension of the disease, said that as no case had occurred in Dublin for 200 years, an entirely new problem was presented. Some connexion with the shipping of the port might have been expected, but this patient had none, except that she lived near the docks. She had, however, a pet cat which slept in her bed, and which was in the habit of disappearing at intervals. This animal might have been infected by rat fleas, but it was not possible to ascertain the fact owing to its prompt destruction by the sanitary authorities. No unusual mortality had been noticed among the rats at the docks, and the specimens examined were negative as regards plague. The usual measures of disinfection were adopted, and the health authorities in England and Scotland were notified. As no further case had been reported after the lapse of nearly two months, this would probably prove an isolated case.

Dr. W. F. LAW had never seen a case of plague in his colony (British Guiana), but it had occurred in Trinidad on two occasions to his own knowledge. He was surprised to hear that direct infection played such a prominent part; he thought the rat flea was generally accepted as the infecting agent.

Sir J. W. MOORE thought the introduction of plague into this country quite a possible event. A relative in the Royal Navy had told him on his return home after visiting Algiers and Lisbon that plague existed in Algiers and in Lisbon, both places in fairly close communication with the British Isles.

Dr. SPEARES instanced an outbreak in a family in Malta, two members of which died before the diagnosis was made. The laboratory attendant punctured his finger during an autopsy on one of the cases, developed plague, and died.

Dr. SYGNE described the gland removed by Sir Arthur Ball:

It was about 1½ in. in length. It was oedematous and hemorrhagic. Smears from the gland showed very large numbers of Gram-negative bacilli. These bacilli were short and thick, and

stained darkly at both poles, the centre of the bacillus remaining unstained. Cultures on blood agar after thirty-six hours showed small whitish-grey colonies. These consisted of bacilli similar to those found in the direct smears of the gland. Cultures on salt agar after three days showed marked involution forms. A guinea-pig injected with material from the gland died after seven days. It showed general oedema with areas of congestion. The gland in the groin was much enlarged, oedematous, and haemorrhagic. The spleen was greatly enlarged and studded with large numbers of white spots. Smears of the glands and spleen, and cultures from the glands, spleen, and heart's blood all showed bacilli similar to those found in the patient's gland. A culture from the patient's blood on the seventh day of her illness was positive, but bacilli were not seen in a direct examination of blood films.

The morphological and cultural appearances and the result of animal inoculation proved that the bacillus found in the patient's gland was *B. pestis* and that the patient was suffering from bubonic plague.

Dr. DUFFY, in reply, said that the entire credit of the case was due to Sir A. Ball, who recognized the inflamed gland as something unusual, and to Dr. Syngé, who had the courage to make what appeared at first a very improbable diagnosis. He did not suggest that direct infection in plague was a common route, but it had been shown to occur. He thought antipneumonic serum more useful in prophylaxis than in treatment.

"VICARIOUS MENSTRUATION."

A MEETING of the Obstetrical Section of the Royal Academy of Medicine in Ireland was held on December 10th, 1920, with the President, Dr. E. HASTINGS TWEEDY, in the chair.

Dr. BETHEL SOLOMONS read a paper on herpes as a type of vicarious menstruation. He reported a case which had been referred to him by Dr. Wallace Beatty.

The patient was a girl aged 27, who complained of getting a sore on the left cheek every month, which Dr. Beatty described as catarrhal herpes. Bimanual examination under anaesthesia revealed absence of the essential genitalia. It was thought well to confirm this diagnosis, and the abdomen was opened. It was then seen that a candle-like structure passed from one internal abdominal ring to the other, and that the uterus, tubes, and ovaries were absent. On a further search, an ovary of normal size was found attached to a very thin fold of peritoneum, which was in such a position that it might have been intended to represent the broad ligament, and the ovary was anterior to this. There was no ovarian or ovario-pelvic ligament, and the ovary was obviously obtaining its blood supply from the peritoneum in which it was nestling.

Dr. Solomon, having discussed the question, considered that the case might be ranked as one of vicarious menstruation.

Dr. SPENCER SHELL agreed with many present-day authorities that vicarious menstruation did not exist. In cases of pink discharge coming monthly from axillae neither red cells nor haematin were found in it. He looked upon herpes as a very common accompaniment of menstruation, as were headaches, swellings, etc. These symptoms increased in menstrual derangements, and were merely manifestations of vasomotor disturbance due to internal ovarian secretion. Where periodical haemorrhages occurred—for example, epistaxis—local causes had invariably been found which, when treated, removed the so-called vicarious menstruation.

Mr. A. K. HENRY said that menstruation involved notable vasomotor changes, and these were controlled by the autonomic nervous system, a system which, taken as a whole, was concerned with widespread reactions. Dermographism, for example, was described as being specially pronounced in certain individuals during menstruation, and it was possible to account for this, and for catamenial herpetic eruptions, by a diffusion of exaggerated vasodilator response, or, as in Dr. Solomon's case, by a complete directing of vasomotor effects into extragenital channels. In dermographism urticaria was simulated, while in herpes the results of vasomotor activity proceeded to the formation of vesicles.

Dr. SOLOMONS, in reply, said he was one of those who believed that vicarious menstruation did exist. It was open to question whether his case was actually an example of the condition. According to Dorland's definition, it certainly was. All drug treatments had been tried, and still the herpes recurred every month. He did not remove the ovary, as he thought the absence of its secretion would be more harmful to the girl than the presence of the herpes.

Rebuelus.

SCURVY.

In *Scurvy. Past and Present*,¹ Professor A. F. HESS has provided a very complete and well written monograph on this most important subject. At the present time a large amount of literature is rapidly accumulating, greatly stimulated by conditions produced during the war; much of this literature, though valuable in quality, is difficult of access, and this the author has gathered together and placed before the reader in a manner most helpful and interesting. The book is divided into eleven chapters, dealing with history, etiology, the antiscorbutic vitamins, pathology, experimental scurvy, antiscorbutic foods, symptomatology and diagnosis, prognosis, treatment, metabolism, and relation to other diseases. It contains a number of illustrations, diagrams, radiograms, and a good bibliography; it is practically free from errors or omissions.

The very great experience of the author, both in animal experimental work and in clinical observation on infantile scurvy, renders his deductions of the greatest value. At the outset he makes it clear that there is no etiological difference between adult and infantile scurvy, and that the prevalence of the latter is far greater than is generally recognized, owing to the increased use of artificial foods, which are practically all deficient in antiscorbutic vitamins. He believes that infants brought up on natural milk do not contract scurvy, and he places a rather higher value on unheated cow's milk than is assigned to it by the workers at the Lister Institute. While recognizing that pasteurized and boiled milk are very inefficient, he holds that the value of milk is not appreciably diminished by the rapid drying method used in the Just-Hatmaker process; if so, it is a very valuable and practical substitute for raw milk. He states that there is no basis for assuming an inter-relationship between infantile scurvy and rickets; scurvy, he says, will develop as rapidly when rickets is absent as when present; in practice, however, the two diseases often are present together. For prophylaxis and cure the author would place the greatest reliance on raw orange and lemon juice or strained canned tomato, but he recognizes that germinating pulses and the juice of swedes are of very high value; for infants of one month old he recommends the addition of one teaspoonful of orange juice daily, believing that it is not wise to wait, as is the common practice, until the fifth or sixth month.

There is so much in each chapter of intense interest which might call for comment that it is impossible to do full justice in a review, but we will draw attention to only one more observation—namely, the necessity of early diagnosis in the pre-scorbutic stage, which is far too often unrecognized; frequently, in fact, the diagnosis made is "rheumatic." The experience of Comby with infantile scurvy emphasizes this graphically; of 55 cases, the diagnosis was erroneous in 45, the infants being treated with sodium salicylate when they were in reality suffering from infantile scurvy.

With regard to foods, the important factors are not only the initial vitamin content of the substance, but the methods of preparation, amount of heat used, the time of storing before use, and the amount taken; for instance, though potatoes contain only small quantities of active antiscorbutic substance, yet they are so widely and largely used that they must be classed as most powerful antiscorbutics. This book comes at a very opportune moment, and should be carefully read and acted on, especially by those interested in child welfare at the present time; the author is to be congratulated on the justice he has shown to every known author—no mean accomplishment.

P. W. B.-S.

ORTHOPAEDIC AND RECONSTRUCTIVE SURGERY.

Dr. ALBEE's work on *Orthopaedic and Reconstruction Surgery*² is one of extraordinary interest to the ortho-

¹ *Scurvy, Past and Present*. By Alfred F. Hess, M.D., Clinical Professor of Pediatrics, University and Bellevue Hospital Medical College, New York City. Philadelphia and London: J. B. Lippincott Co. 1920. (Demy 8vo, pp. 235; 25 figures. 18s. net.)

² *Orthopaedic and Reconstruction Surgery: Industrial and Civilian*. By Fred. H. Albee, A.B., M.D., D.Sc., F.A.C.S., Philadelphia and London: W. B. Saunders Co. 1919. (Roy. 8vo, pp. 1138; 221 figures. 6 plates. 50s. net.)

paediatric specialist and to the operating surgeon. But it is so personal and the lines of treatment advocated are so often contrary to the accepted teaching that it can scarcely be recommended to the student. It deserves to be widely read, and will, no doubt, be widely criticized, for it extends the author's well-known methods of utilizing mechanical assistance in operating so as to make them applicable to the whole realm of orthopaedic surgery. Dr. Albee is a mechanic of first-class ability; his mechanical genius and his manual dexterity have led him to suggest ingenious operations for many conditions which most orthopaedic surgeons will prefer to treat by other and simpler means. But, after all, this is a common failing with pioneers, and the great advances in surgical technique which the author has initiated can be trusted to find their proper place as they are adopted and tested by other surgeons and subjected to external criticism. Each section contains a condensed but adequate account of the etiology, symptoms, pathology, and diagnosis of the condition under discussion, followed by a good account of the principles of treatment and of the methods generally used. The particular methods of the author are described in great detail, and it is here that the book is most open to criticism. Seldom is some clever method of operative treatment wanting; for example, Albee's method of fixing the spine by a bone graft is already well known and tested, but here are methods of fixation by a bone graft in tuberculous disease of the hip, knee, ankle, tarsus, carpus and shoulder. Paralytic scoliosis, congenital dislocation of the hip, congenital talipes, fracture of the patella, and slipping patella are only a few of the other conditions amenable to treatment by the bone graft. The reader must understand that these methods are new, and that he must regard them in a critical spirit and with an open mind, refusing, perhaps, to accept them as of proved efficacy, but pitting them against other accepted methods of treatment. These new methods must thus act as a stimulus to progress in reconstructive surgery. The descriptions throughout are good and the illustrations copious and excellent. There need be no failure to understand the author's methods. Good bibliographies are added in each section, and these and the text show that the literature has been carefully studied and digested. This is particularly true of the accounts of the more rare conditions, which are described with a brief accuracy which is rare in a textbook. The order of the chapters and sections is open to criticism. Thus the first chapter contains a series of valuable general principles, which are, however, placed in a remarkable order so that succeeding paragraphs are headed, "The Position of Neutral Muscle Pull," "The Portable X-ray Apparatus," "Ankylosis," and "Referred Pain." Again, the chapters on tuberculous disease are interrupted after tuberculosis of the spine, whilst chapters on bone-grafting, Roentgenology, and the electro-operative bone outfit are inserted. However, these vagaries do not detract from the general excellence of the book, and it may be said that the education of the up-to-date orthopaedic surgeon is incomplete until he has studied it.

Mr. P. B. Roth's *Orthopaedics for Practitioners*³ is a book of a very different sort. For the most part it consists of a brief but clear account of the more common deformities, and the principles of their treatment; but it also is open to the criticism that it is in many respects too personal. The author is too apt to condemn off-hand all those methods of which he does not approve. Scoliosis is to be treated by gymnastic methods; correction in structural cases is, in Mr. Roth's opinion, impossible, and therefore must not be attempted. Such views, if extended to the whole of surgery, would stop all progress. Moreover, certain methods accepted by most surgeons are subjected to equally brief condemnation, and in several instances if the student accepts the author's views without question he might find himself in difficulties with an unbiassed examiner. This work again, then, but for different reasons, needs to be read in a critical spirit; if allowance is made for the individuality of the opinions put forward, it may be recommended as a good elementary manual for the student and practitioner.

³ *Orthopaedics for Practitioners*. By Paul Bernard Roth, M.B., Ch.B., F.R.C.S. London: Edward Arnold, 1920. (Demy 8vo, pp. 195; 57 figures. 10s. 6d. net.)

THE SEX COMPLEX.

In the second edition of his book *The Sex-Complex* Dr. BLAIR BELL has made such additions and amplifications as serve to bring it up to date. Despite its vastness and complexity the subject of endocrinology is so fascinating that in the last few years a literature, which is really far too great in bulk, has grown up around it, and it has become a labour worthy of an intellectual Hercules to thresh the grain from the chaff. Verily there is scarcely a subject in medicine about which the same could not with some justice be said in these days, but in regard to this particular one the necessity of a finely balanced judgement in making and in interpreting both the experiments and the clinical observations which must form the foundation of any real progress is particularly apparent, and a large percentage of the literature might with advantage be "scrapped." With feelings such as these one comes to Dr. Blair Bell's book with a sense of refreshment, for here is a successful effort to produce as much of order as is at present possible out of the chaos in one portion of the vast field. Gynaecologists in particular will welcome the work, for in every chapter there is food for thought, and for reasoned speculation as to the probable future developments of their art in relation to functional diseases.

Compared with the first edition, the present volume differs mainly in the matter of additions. The appendices to the former have been embodied in the text, and perusal has been facilitated by the introduction of subject indexes in the margin. The discussion of sexual and reproductive psychoses and neuroses has been considerably elaborated, and the author is to be congratulated on the courage with which he has tackled a delicate and thorny question. We notice that he has given up his former view that the uterus might prove to be an organ of internal secretion. He now regards "uterin" rather as the external secretion of that organ. The claims of the placenta to a place amongst the hormonopoeitic glands he also effectively disposes of. All recent reliable gynaecological researches point to the correctness of the view which Dr. Blair Bell emphasizes as to the absolute interdependence of the individual metabolism of a woman and her reproductive metabolism, and in this work he produces much evidence to support his well known contention that in the calcium metabolism is to be found the key to the problem of how the two are linked together.

We hope that the author will reconsider his decision, as stated in his preface, not to publish another edition. This is the sort of book of which gynaecology requires a new edition every four or five years.

A NATURALIST'S STUDY OF SLEEPING SICKNESS.

IN 1910 Dr. G. D. HALE CARPENTER was sent by the Tropical Diseases Committee of the Royal Society to Uganda to study the tsetse fly *Glossina palpalis*, which had been known since 1902 to be the carrier of sleeping sickness. From February, 1911, to the outbreak of war, with an interval in England, his time was spent on the islands in the north-west portion of the Victoria lake. In a book recently published, *A Naturalist on Lake Victoria*,⁵ he gives an account of his studies of the fly and records a number of observations on the fauna of the islands. These islands, which vary in size between the area of Rutlandshire and mere rocks, were at the close of the last century supporting a thriving population, but the sleeping sickness epidemic, the existence of which first became known in 1901, carried havoc among the inhabitants, and with a view to saving the remainder the Government, about 1907, removed them all. Apart from their beauty, the islands have an advantage over the mainland in that malarial mosquitoes are rare—Dr. Carpenter's party never suffered from fever—and the ticks that suck and incidentally infect cattle, as well as the dreaded *Ornithodoros*, are nearly if not altogether absent; so that apart from tsetse

⁴ *The Sex-Complex. A Study of the Endocrine Glands and their Influence on the Internal Secretions to the Female*. By W. Blair Bell, M.D., F.R.C.S. London: Baillière, Tindall, and Co. (1920. 21s. net.)

⁵ *A Naturalist on Lake Victoria, with an Account of Sleeping Sickness and the Tsetse Fly*. By G. D. Hale Carpenter, D.M., B.Ch. London: T. Fisher Unwin, Ltd. 1920. (Med. 8vo, pp. 357; 87 figures, 2 plates, 1 map, 4 charts. 25s. net.)

they are desirable both for man and beast. Knowledge of their natural history, therefore, should be of value as well of interest.

In the first chapter a historical account of sleeping sickness is given, beginning with the description by John Atkins, surgeon, published in 1742, and coming down to the great epidemic in Uganda, which is said to have carried off 200,000 natives, and the more recent discovery of the disease in a rather different form to the south, "rhodesiense sleeping sickness," so called from the specific name given to the trypanosome. The next chapter deals with the natural history of the disease, and we find a description of the situtunga antelope, *Tragelaphus spelei*, believed to be a natural host of the "human" trypanosome in that region, and hence an essential link in the chain of endemicity. As one of the results of the depopulation the situtunga, being good swimmers, invaded several islands, where they were previously unknown, and in this way Dr. Carpenter accounts for the infection of three of his native employees. In the chapter on the natural history of *Glossina palpalis* the author incorporates his work for the Royal Society published in the Sleeping Sickness Reports. He studied especially the breeding places, the fly's foes, and the fly's food. He showed that the fly feeds chiefly on the varanus lizard, an amphibious creature which reaches a length of six feet, to a less extent it feeds on the crocodile, the insect avoiding the formidable barrier offered by the scaly skin by choosing an eyelid, even on islands where situtunga are present only one fourth of the fly's food is obtained from them. The favourite breeding places Dr. Carpenter found, are raised shaded beaches, well above the water line. He devised a plan of constructing artificial or decoy breeding grounds so attractive that they are preferred above all other places; by a periodical collection of pupae he hopes that an appreciable impression may be made on their numbers. The fly's enemies are not numerous, and there seems to be little likelihood that the state of equilibrium now reached can be upset in this way, unless it be by the aid of parasites of the pupae. The Uganda canoe is described as "a link between a dug out and a built vessel," but it served for a tour among the northern islands with Mr. Fiala, who was in Uganda on a like mission. The object of the voyage was a comparative survey of the islands, and note was taken of the butterflies "as some sort of index to the general suitability of an island for insect life." In some islands the webs, several feet in diameter, of great spiders, a species of *Nephila*, were so abundant as to make progress difficult as well as unpleasant. Tsetse was caught on nearly all the islands and pupae were found on one as small as 200 by 50 yards. There is, Dr. Carpenter says, no exchange of fly between even adjacent islands, they do not cross open water.

In the course of a description of the fauna, the hippopotamus, monkey, otter, mongoose, bat, and situtunga are mentioned. The last, it is said, is multiplying rapidly, it browses on bushes near the water (where the fly feeds upon it) instead of, as elsewhere, leaping to the swamps, and with the change in its habits there seem to be some modifications in its structure—changes in the horns and hoofs. The birds described are numerous, but we must not tarry with them. Crocodiles were scarce, and this was attributed to the absence of man, the varanus preys on crocodile eggs the natives hunted the varanus for its skin. In the absence of man the varanus has multiplied, and the crocodile families have decreased, from one nest there disappeared in seven days seventy six eggs. In the description of snakes which include poisonous snakes and pythons it is said that the booming noise of the crowned crane is put down by the natives to the puff adder.

In recording his observations on the coloration of insects Poulton's classification into apatic or "deceitful" colours and sematic or "warning" colours is adopted. Apatic colours are procyptic or anticyptic. Procyptic coloration conceals its wearer from danger—for example, a green grasshopper among grass—and in these instances attracting the action of natural selection there are neuro-miscular changes as well. Anticyptic coloration enables animals to obtain their prey. Instances are some mantidae. The consideration of aposematic coloration, bright colours which are regarded as "warning" leads on to the subject of mimicry, to which this chapter, and especially the next on the polymorphic butterfly *Pseudacraea eurytus*, form a

valuable contribution. Dr. Carpenter, by breeding from known individuals, succeeded in establishing this butterfly as "one of the greatest examples of mimicry in the world" (Poulton). The concluding chapters treat of hymenoptera and sundry insects. A locustid, known to the natives as "semukutu," is of medical interest in that when handled it ejects from the side of the thorax a stream of clear yellow fluid with an acrid smell which causes sores on the skin, Carpenter, however, handled many without ill effect.

The book is well illustrated with good photographs, it contains a serviceable map, and, as Professor Poulton writes, a really wonderful body of observations. The style is attractive, and the work will, we predict, find many appreciative readers.

PRACTICAL PHARMACOLOGY.

PROFESSOR DIXON'S *Practical Pharmacology*⁶ is intended for the use of medical students, such as those at Oxford and Cambridge, who do practical work in their pharmacology courses. The experiments described are simple, and have been selected to illustrate well recognized actions of common drugs in everyday use. None of the experiments are intended for demonstrations on decerebrate mammals. The book contains twelve chapters, dealing with the effects of drugs on organisms and organs of various kinds, their excretion in the urine, and the physical properties of certain medicaments. For the experimental pharmacologist's benefit a useful table of doses for animals is given in an appendix.

Professor Dixon writes clearly and to the point, and his text is full of important practical considerations of service at the bedside as well as in the laboratory. The text is illustrated with a number of serviceable diagrams. The book should be of great assistance to medical students, to whom it may be warmly recommended.

NOTES ON BOOKS.

DR. JOHN HIRST of Philadelphia has prepared a *Manual of Gynecology*, in which much care has been taken in the description of operations, but in some places it might have been better to give more space to the symptoms and signs of the disease and less to the many methods described for its treatment. The student will greatly appreciate the instructions given for the prescription and application of the drugs so frequently used in palliative treatment, for in many textbooks this important subject is merely outlined, and the student is left in doubt as to how treatment is to be applied in practice. Leucorrhoea and vaginal discharges are discussed in a special chapter, and a good deal of space has been allotted to the consideration of diseases of the heart and rectum, on the ground that affections of these organs must often be treated by the gynaecologist. The chapter on electricity, x rays and radium is well done, but the information given as to organotherapy is chiefly borrowed. The properties of animal extracts are described, and it would appear that the author has a good deal of faith in their value. The book contains many illustrations, none of them exactly artistic, and possesses a good index.

The third edition has appeared of *First Aid in Emergencies*,⁶ by Dr. ELDRIDGE ELIASON, it brings up to date this useful little manual for the lay public by the inclusion of new chapters on methods of fixation and dressing of fractures for transportation derived from the lessons of the war on recent antisepsis as applied to first aid, and on simple precautions in infectious diseases.

The latest edition of the long established year book, *Fry's Royal Guide to Charities*,⁷ gives in compact form a classified list of the chief charitable institutions, with date of foundation, annual income, objects, etc., and a special feature is made of the editor's guiding notes.

⁶ *Practical Pharmacology* For the Use of Students of Medicine. By W. L. Dixon, M.A., M.D., F.R.S. Cambridge: At the University Press, 1920. (Demy 8vo pp. 83, 16 figures 7s. 6d. net.)

⁷ *A Manual of Gynecology*. By John Cooke Hirst, M.D., Philadelphia and London: W. B. Saunders Co. 1918. (Crown 8vo pp. 455, 170 figures 12s. net.)

⁸ *First Aid in Emergencies*. By Eldridge E. Eliason, M.D., F.A.C.S. Third edition, enlarged. Philadelphia and London: J. B. Lippincott Co. 1920. (Crown 8vo pp. 215, 166 figures 7s. 6d. net.)

REFORM IN MEDICAL EDUCATION.

[FROM A CORRESPONDENT.]

(Concluded from page 53.)

III.

THE TEACHING OF MEDICAL ETHICS.

REFERENCE may next be made to what, in point of time, was the first of the subjects dealt with in the present movement for improvement of medical education. In 1915 the Council adopted the following motion:

"That it be remitted to the Education Committee, with the addition for this purpose of Dr. McVail and Dr. Newsholme, to report to the next meeting of Council on the education of medical students in the ethical relationships of medical practitioners to the State, to their patients, and to each other, and that the Committee have power to make such inquiries on the subject as it deems advisable."

The term "medical ethics" presumably means the application to medical practice of the theory or science of moral obligation. After the Council had adopted the resolution just quoted a letter was addressed to all the teaching bodies, which in most cases elicited the reply that the subject was dealt with in the courses of forensic medicine and public health, but that in a number of instances there had been no regular instruction. The Committee was of opinion that the subject should not be neglected in the education of the medical student, but recognized that the arrangements for conveying the instruction might naturally vary. It therefore proposed that the following general recommendation be added to the resolutions of the Council in regard to professional education:

"Instruction should be given, in the courses of forensic medicine and public health, or otherwise, on the duties which devolve upon practitioners in their relationship to the State, and upon the generally recognized rules of medical ethics. Attention should be called to all notices on these subjects issued by the General Medical Council."

The resolution was adopted by the Council. In November, 1919, it took the matter up again and remitted to the Education Committee to make further inquiries as to the instruction then being given to the students. Replies were received from twenty-six bodies and in general indicated that effect was being given to the recommendation of the Council. The Committee was of opinion, however, that the reminder had been useful in some cases, and a number of the bodies promised to give the subject more attention in the future.

In the communication made to the licensing bodies their attention was directed to the "Warning Notice" issued by the Council so that medical students should have pointed out to them what they had to avoid under its terms. The Notice has had gradually to be made more inclusive as a result mainly of additional legislation. It is divided into six sections: (1) Certificates, notifications, reports, etc.; (2) unqualified assistants and covering; (3) sale of poisons; (4) association with unqualified persons; (5) advertising and canvassing; and (6) association with uncertified and women practising as midwives. One object of the Council, therefore, is to prevent a practitioner from heedlessly committing an act which would involve him in a charge of infamous conduct in a professional respect. Section 2 of the Notice, relating to unqualified assistants and covering, is much less necessary now than when it was issued; this offence has receded into the background. The same may probably be said of Section 4—association with unqualified persons. On the other hand, one or two cases under Section 6—association with unqualified midwives—have been before the Council in quite recent years, and the scope of Section 1 in relation to certificates, notifications, etc., has been widened both owing to fresh legislation and to questions arising in connexion with the war.

Certificates required for a variety of purposes are valid only if signed by a qualified medical practitioner. Such a certification is therefore a medical privilege, as well as a medical duty, and it is of the utmost importance that the duty be performed with every possible care. There may be now and then a natural tendency in granting a certificate to do something to oblige a friend or a patient, but the most scrupulous rectitude is essential. Fundamentally, the principles of ethics are of universal application to every profession and to every man, but the medical profession, on account of its special responsibilities, has to walk very warily, not merely to avoid infringing the rules of the

General Medical Council, but to maintain the honour and repute of the profession in the public estimation. All this being so, the Council does well to recommend the instruction of students in medical ethics.

In its relation to "infamous conduct in a professional respect," the Council is perhaps at a disadvantage in having no machinery for making inquiries or investigations on its own account. The criminal authorities throughout the country are required to report to the Council every conviction of a practitioner for a felony or misdemeanour, and such cases, after consideration by the President and the Penal Cases Committee, are frequently brought before the Council. In the absence of a conviction evidence of alleged infamous conduct has to reach the Council by way of complaint by any individual or public department, etc., believing itself to be aggrieved, or by a body acting in the interests of the profession, such as the British Medical Association or one of the medical defence organizations.

The Council is also at a disadvantage, at least theoretically, in respect of the fact that it has only one kind of punishment which it can impose. That punishment is very drastic. It is the removal of the name of the practitioner from the *Medical Register*. Since the institution of the Council in 1858, however, this difficulty has been in a considerable measure overcome. Though the facts alleged against a practitioner may be held by the Council as proved, judgement may be suspended and the doctor in question required to present himself at a subsequent meeting of the Council, and to submit evidence by medical practitioners or other persons of standing that he has in the interval been acting in every way in consonance with proper standards of conduct. In such circumstances, after admonition by the President on behalf of the Council, no further action may be taken. Occasionally the period of probation may be prolonged beyond the six months which intervene between one meeting of the Council and another, or a practitioner may be required to come before it for a second time, and to bring further testimony on his behalf. Even where a name is removed from the *Medical Register* it may be restored, on application, after a sufficient interval and on consideration of what may have taken place since the removal of the name. By such expedients—and this statement of them is not exhaustive—the Council has had a measure of success in establishing something equivalent to a series of penalties corresponding to the greater or less gravity of the offence.

REVISION OF THE REGULATIONS AND RULES FOR
DIPLOMAS IN PUBLIC HEALTH.

This is the very latest direction in which the reforming zeal of the Council is manifesting itself. On the last day of the recent session the following resolution was adopted by the Council at the suggestion of the Public Health Committee:

"That the General Council authorize the Public Health Committee to consider and revise the existing regulations and rules for diplomas in Public Health which were originally adopted by the Council on June 1st, 1889, and amended and amplified from time to time, particularly on December 1st, 1911, with a view to bringing the special course of instruction required of candidates for the diploma into harmony with the duties of a modern medical officer of health, which have changed considerably since the resolutions and rules were originally adopted and afterwards amended and amplified."

The Council, it should be pointed out, is in a much stronger position with regard to Public Health diplomas than with regard to qualifications in medicine. As concerns the latter, it has already been observed that the Council can only make "recommendations" to the licensing bodies, and that its ultimate control consists in advising the Privy Council to refuse registration to the licences of any persistently recalcitrant body. As to diplomas in Public Health, however, its power is absolute excepting that, of course, it lies with the licensing bodies to carry out the rules and regulations laid down by the Council. When the rules were originally adopted in 1889 the conception of public health was comparatively elementary. Excepting for infectious diseases and epidemiology in general, it related wholly to matters of environment, to water supply, food and milk supply, drainage, cleansing, ventilation, nuisance prevention and removal, and the like. Within recent years there has been extensive development, and such duties as school medical inspection and treatment, maternity and child welfare, and control of venereal

disease have come within the scope of the Public Health authorities. It is right, therefore, that the requirements for diplomas in Public Health should be correspondingly altered.

The discussion which took place on submission of the motion indicated that the Public Health Committee had in view not merely the question of adding new items to the required course of study, but the question whether at present too much time is not devoted to chemistry and bacteriology, seeing that in practice medical officers of health are not required to carry out this kind of work. They should always be able, however, to appraise the value of reports and certificates by analysts and bacteriologists.

Conclusion.

This completes the survey of the proceedings of the General Medical Council in regard to reform of medical education. It will be seen that the whole curriculum is under review, and that the questions include the raising of the age at matriculation from 16 to 17 years; stiffening of the preliminary examination in general education; a new preliminary examination in the introductory sciences; the subsequent teaching of these sciences in their application to the later stages of study; the inspiration of the entire curriculum with the principle of maintenance of health, and the preventive treatment of disease in its earliest and most trivial manifestations; revision of every section of the curriculum for excision of whatever is unnecessary, and for addition of whatever matters of moment may have hitherto been omitted; co-ordination of the whole educational scheme for avoidance of overlapping and for the due ordering and sequence of the subjects; modification of the examination system by introduction of the candidate's record of work throughout his years of study as an element in determining his admission to the practice of medicine; definite education of the student in the application of the principles of ethics to the sphere of medical practice, along with instruction in his duty to the State, and in the provision made by the State for supplementing the work of the practitioner in respect of health at every stage of life; and revision of the course of instruction and study required for diplomas in Public Health.

The scope of the movement in which the General Medical Council is now engaged could hardly have been wider. It is to be hoped that undue haste and undue delay in arriving at momentous decisions will alike be avoided. There is no doubt that the proceedings of the Council will be watched and its conclusions considered with appreciative interest by the general body of the medical profession

THE NEW INCOME TAX.

WHEN the Royal Commission on the Income Tax issued its very able report we called attention in some detail to the probable changes which it would bring about in the income tax system. As our readers are aware, some of those proposals have been translated into fact, and the payments of tax now being required all over the country are the first to be determined by the fiscal changes effected by the Finance Act of 1920. Income tax has for some years been at such a level as to make a very real inroad on the enjoyment of the income; it represents a surrender to the State of purchasing power only too urgently desired in these days for the legitimate satisfaction of present and future wants, and it is important that demands made by the local officials should not be satisfied until they have been subjected to intelligent examination. Fortunately, the new system is in many respects simpler than the old, and we very strongly advise all taxpayers to see that they understand what they pay before they pay it. This may, and not infrequently does, involve a little trouble, first, in studying the regulations, and second, in clearing up any obscure points or errors with the local officials, but it is time very well spent, and it will, as a rule, be found that the officials are willing to discuss such matters in an intelligent and helpful manner. We propose here to set out the elements of the new system as briefly and clearly as possible.

First, of all, the change, radical as it is, does not in any way affect the calculation of the "income" which is to be taxed, professional profits remain assessable on the basis of the average of the three previous years' earnings, untaxed

interest on the basis of the previous year, and so on. What the change does is to sweep away the old system of the two scales of rates—for earned and unearned incomes—rising at each £500 of total income, and substitute for it a new method of raising the effective rate as the total income increases, while at the same time the man with family dependants receives not insubstantial relief as compared with the taxpayer whose income is not required for the support of others beside himself.

1. Earned Income.

Income earned directly by the taxpayer is still dealt with less stringently than unearned, or, as it is now called, "investment" income, but to avoid the complication introduced by a different rate of tax that object is achieved by deducting 10 per cent.—that deduction, however, is not to exceed £200 for any individual—from the earned income, the balance of 90 per cent. being called the "assessable income." Where the income is mixed—that is, partly of each class, earned and unearned—the "assessable income" is, of course, the whole less 10 per cent. of the earned income—for example:

A. has £500 "earned" and £500 "investment income"—that is, his "assessable income" is £500 - £50 + £500 = £1,310.

A clear grasp of this conception of "assessable income" is essential to a proper understanding of the present system.

2. Allowances.

It is important to remember in this connexion that the income limit which formerly applied to this class of relief has entirely disappeared. If the ground for the claim exists, it holds good irrespective of whether the total income of the individual is £300 or £3,000. By way of warning, however, it may be pointed out that these allowances do not apply to super-tax, though they apply to the income tax payable by the same individual.

The allowances are deductible from the assessable income, and may be summarized as follows:

	£
Personal, unmarried	135
Personal, married	225
Personal, wife, as regards own earnings, additional	45
Child—for one, complying with the stated conditions	36
Child—for each other one, complying with the stated conditions	27
Relative taking care of widower's or widow's child	45
Relatives dependent by old age or infirmity, and not having an income exceeding £50	25

The revenue authorities have forms containing the declarations required to be made when claims under the above heads are lodged, and we understand that such forms are supplied on application to the office of the local inspector of taxes.

3. Assessable Income.

When such allowances as are due have been deducted from the assessable income the balance is chargeable to the income tax, and it is provided that the first £225 of that balance shall be charged at 3s. in the £ and the remainder at 6s. It is the fixity of the portion—or "slice"—of the income chargeable at 3s. which produces the graduation of the tax. A moment's thought will serve to show that the greater the total income the greater proportionately the "slice" paying at the 6s. rate, and therefore the higher the effective rate—that is, the rate arrived at by comparing the total income with the actual amount of tax paid. In passing, it may be remarked that the stiffening of the super-tax accentuates the graduation as regards the higher incomes.

It may serve to make the matter clearer if the method is set out in the form of a calculation as follows:

Amount of total income	£
Deduct one-tenth of earned income	£
Assessable income	£
Deduct allowances	£
Income chargeable to tax	£

Of this amount £225 is chargeable at 3s. and the remainder at 6s. in the £.

Life Assurance.—Under the old scheme the allowance for life assurance premiums was treated in the same way

as other allowances—at any rate so far as “old” policies, that is policies taken out on or before June 22nd, 1916, were concerned—they were deducted from the taxable income so that the payer benefited more or less according as he paid a higher or lower rate of tax. This principle has been preserved by providing that, so far as “old” policies are concerned, an allowance is to be given as follows:

Where the total income does not exceed £1,000, at 3s.
Where the total income does not exceed £2,000 at 4s. 6d.
Where the total income exceeds £2,000, at 6s.

As result of this, the duty calculated at 3s. and 6s. in the £ has to be reduced by the appropriate amount of the life assurance allowance calculated in terms of actual tax. “New” policies carry a relief at a uniform rate of 3s. in the £ as before.

One or two points remain to be noted. It is provided by Section 17 of the Finance Act, 1920, that the individual claiming the allowance must make a statement of his total income in the prescribed form. The stipulation is presumably intended to prevent an individual who has incomes in different areas being given any particular allowance twice over—a result which might happen when separate returns were being made to different officials. It is possibly this stipulation which has led to the withholding of the allowance in some of the cases which have been discussed in the daily press. Where the total income is under £2,000, it has for some years been the practice to render to the local authorities a statement of the total income, and where that has been omitted by accident or neglect the taxpayer's best course is to make good the omission and obtain a rectification of his assessment as soon as possible.

But where the total income exceeds £2,000 the position is different. In those cases the taxpayers are called upon to make returns to the London office of the Special Commissioners for the purpose of super-tax, and may very reasonably object to supplying similar statements to another official. We understand that in such cases the Special Commissioners have supplied forms of claim to individuals on their books, and, on receiving the declarations back, have notified the person in question as to whether the allowances are being made (1) through the inspector's office against tax payable locally, or (2) by the Special Commissioners themselves by way of set-off from the charge for super-tax. Where the former notification is received it would seem advisable to see that particulars of the revised assessment are supplied by the local inspector.

The advantage of the new system is that income received from investments is in the normal case taxed at 6s. in the £ by deduction, and usually properly so taxed. So long as the various “allowances” and the relief afforded by the £225 at 3s. provision are made against that portion of the income which is not taxed at its source, and therefore comes before the officials for assessment, then the amount of the investment income is immaterial, and the old trouble of determining on which side of a particular £500 limit line the total falls is avoided.

The new system has strong recommendations and obvious advantages, and there is good ground for hoping that it will materially assist the ordinary taxpayer to understand not only how much he has to pay, but also how the amount is properly determined. That consummation will be brought much nearer by a little trouble and thought on the part of both the taxpayer and the revenue authorities.

AMERICAN CONGRESS ON VENEREAL DISEASE.

At the International Health Congress held at Cannes in April, 1919, the delegates representing the five principal allied nations called for regional conferences to take up the campaign against venereal diseases throughout the world. The first of such conferences was held last month in Washington, and among the 400 delegates were representatives from Great Britain, Canada, Argentina, Brazil, Chile, Ecuador, Cuba, Honduras, Mexico, Paraguay, Porto Rico, and Czecho-Slovakia. The second will be held next May in Copenhagen, and will be attended by delegates from all the Scandinavian nations and from Great Britain and

Holland. Later conferences will probably be held in 1921 in Paris and in London, and it is expected that one or both of these will be attended by delegates from Germany.

The meeting in Washington is generally held to have been successful; there were no set papers, and few, if any, set speeches. The work was directed by a general committee selected from the delegates by Dr. W. H. Welch, the President, whose object was to gather together in this committee those who, by their studies, experience, and attainments, and by their relations to other official and non-official bodies, could speak with authority on various phases of the work. Its membership thus included clinicians, pathologists, sociologists, syphilologists, gynecologists, social workers, and psychiatrists. The committee was divided into twelve subcommittees, each being set to consider a special group of problems formulated in a series of questions. In the afternoons the Committee sat as a whole and discussed seriatim the reports furnished by the twelve groups at the morning sessions. While the committee meetings were in progress the remaining 300 delegates assembled in the auditorium of the United States National Museum to hear papers and hold discussions. In the evenings the delegates met to receive the findings of the General Conference Committee, and many of these were keenly debated. The work of editing the resolutions reached by the Conference has not yet been completed, but the general way in which the questions were put forward and answered is shown by the following resolutions adopted in plenary session.

With respect to the use of the Wassermann reaction it was resolved that:

The blood Wassermann reaction should not be used as a sole guide to the duration of a syphilitic infection. The blood Wassermann reaction should not be used as the sole evidence of the effectiveness of a particular drug or method of treatment. The blood Wassermann reaction should not be used as the sole evidence of “cure” no matter how many times repeated.

A further resolution declared that:

The complement fixation test has not yet been shown to be of value in the diagnosis of doubtful cases of gonorrhoea. It is possible, however, that the precipitin test recently reported by Mender and Robinson may be of great value.

The Committee enumerated the advantages of working venereal disease clinics in conjunction with other clinics.

Exhibits and demonstrations were features of the work of the Conference; included in these were the methods of the United States hygienic laboratory in testing salvarsan, the application of the methods of social hygiene by the Washington police, and methods of treating venereal diseases at the United States Naval Hospital. Among the exhibits were wax models of the Army Medical Museum showing phases of venereal disease, and the social hygiene car for educational work now in use in North Carolina was brought to Washington for inspection by the delegates.

THE MEDICAL RESEARCH COUNCIL.

The report of the Medical Research Council for the year 1919-20 is the first annual report of the Council, and includes the work of the Medical Research Committee (National Health Insurance) for the half-year ending March 31st, 1920, and of the Medical Research Council, which was incorporated by Royal Charter on April 1st, 1920, to continue the labours of that Committee, for the half-year ending September 30th, 1920. In spite of the changes in constitutional and administrative control there has been no breach in the continuity of the medical research work supported by parliamentary grant; but the new powers vested in the Council, which are such as have not before been assigned to any body of scientific men, give it fuller opportunities for securing that continuity of policy which is vital to the work of scientific research, and give it wide limits of intellectual and administrative freedom. While the Council is subject to the direction and control of a committee of Ministers responsible to Parliament, its powers are exercised in a position under the Privy Council in which not only is it brought into direct relation to the Ministry of Health for England and Wales, and the corresponding departments in Scotland and in Ireland, but also it can bring more effectively the medical research services throughout the kingdom into relation with the needs of other departments of State, and

¹ Report of the Medical Research Council for the Year 1919-1920. Cmd. 1088; London: His Majesty's Stationery Office, 1920. (91. net.)

with similar systems of research work done in, or for, the various parts of the Empire. The provisions of the Charter make, in fact, a constitutional link of a valuable and novel kind between the scientific forces of the country and the State. As the committee of the Privy Council is under the obligation of consulting the President of the Royal Society before appointing any new member of the Medical Research Council there is a definite and formal link between the Society, as the great unofficial representative body of science, and the official State scientific organization.

Finance.

The increased financial grant of £125,000 made by Parliament for the work of the Council was announced too late in the year to have much effect on the expansion of the schemes already framed, but it has been allocated as follows:

Costs of administration	£ 7,800
National Institute for Medical Research, Hampstead	39,000
Equipment of Institute	18,000
Grants to investigators at universities and elsewhere	60,000

In addition, however, to the lateness in the year of the announcement of the increased grant, other factors are at present limiting the directions and scope of the work which the Council can subsidize. The fall in money value has rendered the increased financial provision more nominal than actual, and the costs of labour and of scientific apparatus have increased in larger ratio even than the decline in money value. In addition, the effect of the war on the universities has caused a dearth at present of men who otherwise could be at the stage of carrying out independent investigations; not only must the investigator be endowed with eagerness and some scientific ability, but he must possess also the requisite equipment in training.

From the report it is apparent that the Council is working in close relation with, and in the interests of, the other departments of State, particularly, as is natural, with the Ministry of Health. This is seen especially in the schemes of work upon tuberculosis and venereal diseases, and in physiology as applied to hygienic measures; less formally the Ministry suggests the need for any new inquiries, in the systems of research work under the Council, by which administrative medical measures may be guided. At the instance of the Home Office, again, the Industrial Fatigue Research Board has been appointed jointly by the Medical Research Council and the Department of Scientific and Industrial Research, in order to direct research on the subject of industrial fatigue on systematic lines, with a view to improving the health and efficiency of the workers; also at the instance of the Home Office new researches into minor's nystagmus have been instituted. For the Board of Trade the control of certain dangerous drugs, and the research work upon which it is based, are still continued. The research grants made by the Council in clinical medicine have been so adapted to the grants for teaching in medicine, formerly made by the Board of Education, as to secure the effective linking of research work with higher teaching. With this in view, the secretary of the Council, Sir Walter Fletcher, was appointed an assessor to the University Grants Committee.

Profitable Lines of Research.

The possible value of research from the purely financial point of view is demonstrated by the fact that after investigations on cardiology, pursued by Dr. Thomas Lewis under the auspices of the Council, for the Ministry of Pensions, approximately £46,000 annually has been saved on cardio-vascular pensions assessments in the London region alone. Recently the Development Commission, in consultation with the Council, has appointed a committee to advise upon the best methods of advancing the scientific study of the diseases of animals, and the hope is entertained that this may lead to the great resources of human pathology, in men, in methods, and in results, being utilized more fully for the study and prevention of animal disease, and in turn that human medicine may gain from the wider outlook and opportunities of comparative pathology.

Research work is being carried out in the direction of setting up official standards of value and authenticity for the numerous biological preparations, serums, and the like

used in medical practice. In regard to such standardization too much dependence was previously placed by this country on the work of public or private laboratories in other countries, chiefly in Germany. The standard, for instance, of the antidiphtheritic serum used in all our fever hospitals, and formerly supplied from Frankfurt, was entirely, during the war, dependent on the fact that the Government of the United States furnished such a standard, while the maintenance of the standard of anti-tetanic serum was likewise due to American enterprise and generosity. For such obvious purposes, as also for the more fundamental purposes of scientific research, biological standardization was urgently required, and both at the institute at Hampstead and the Standards Laboratory at Oxford important work is being done in this direction. The committee appointed by the Council to advise upon improvement and systematization of pathological methods is also continuing its work.

Special Investigations.

In regard to research on specific subjects the period covered in the present report has been one of reorganization. The investigations undertaken for reasons arising directly from the war have now practically come to an end, and in many instances this has been a signal for development along broader lines, and a more general application of the great advances in knowledge in special directions that were gained during the war.

To take one example: in tuberculosis, for instance, the changed conditions have enabled the Council to organize research along the manifold lines of attack offered by the general problem—on the morphology of the tubercle bacillus, on the pathology of infection, on problems of immunity against infection, on the classification of pulmonary tuberculosis, on the early diagnosis of tuberculosis, on the chemo-therapeutic treatment of tuberculosis, on electrical sterilization of milk, and on milk and tuberculosis infections, etc., investigations carried out by different workers in different parts of the country. Other subjects similarly organized for research include cerebro-spinal fever, influenza and pneumonia, rheumatic fever, venereal diseases, problems of child life, disorders of growth, accessory food factors (vitamines), disorders of the cardio-vascular system, the medical problems of flying, biochemistry and chemotherapy, "status lymphaticus," and causes of unexplained death, and many others.

Occupation was resumed during the year of the building and grounds at Mount Vernon, Hampstead, and the several departments which during the war had been isolated in temporary quarters were brought together in accordance with the original design. The expected advantages of daily intercourse between bacteriologists and biochemists, physiologists and statisticians, and others, are being realized, and are giving opportunity for the exchange both of intellectual stimulus and of technical help; free intercourse takes place also between those engaged in schemes of investigation inside the institute and outside it, and several workers from outside laboratories and members of other Government services have been temporarily attached to the institute.

There are many problems in medical science which can best be studied, and some indeed which can only be fully studied, the Council believes, by men engaged in professional practice, who are in a position to follow the signs and results of disease and the effects of given treatment in suitable cases from their earliest to their latest phases. Studies, however, of this kind can only be successful if the professional man has some leisure and if he has access at need to laboratory and other resources, like those of a well-equipped hospital. Studies, again, made in hospital practice may be given the same kind of extended value as those possible to a man in private practice, if the cases can be received in their earliest stages and followed to the end by a proper system of after-history records. The Council expresses the opinion that until some effective revision takes place, both of the conditions of medical practice and of hospital organization, it must remain difficult or almost impossible to arrange for the combined and long-continued observations necessary for successful research work in this field. In this connexion the Council states that it is not only following with sympathy and interest, but has given some assistance to, the Research Institute established by Sir James Mackenzie at St. Andrews.

British Medical Journal.

SATURDAY, JANUARY 15TH, 1921.

PROBLEMS OF MEDICAL EDUCATION.

THE articles in our issues of this month (pp. 20, 52, 88) summarizing the deliberations of the General Medical Council on the burning subject of the reform of medical education, deal with questions of great importance to the future of medicine. They supplement, and indeed in some respects endorse, opinions previously expressed in Sir George Newman's memorandums, "Some Notes on Medical Education in England" (1918) and "An Outline of the Practice of Preventive Medicine" (1919), in the Edinburgh Pathological Club's "Enquiry into the Medical Curriculum" (1918), and by Sir James Mackenzie in various addresses, and particularly in "The Future of Medicine" (1919).

That the first and most important aim of medicine is the prevention of disease may perhaps be said by some to be a truism that is not only recognized but acted upon in many directions, such as infant welfare centres, the school medical service, industrial hygiene, and the social service inspired by the enthusiastic energy of Dr. R. C. Cabot, of Boston, Massachusetts; but the truth is that little more than a beginning, promising as it is, has yet been effected. The scope and meaning of "preventive medicine" perhaps require consideration, for to some minds this term still suggests mainly the activities of the medical officer of health and a specialized branch of medical practice which only incidentally concerns the rank and file of the profession. This mental attitude is probably due to the recollection of the leading part played among the nations by this country half a century or more ago in the organization of a public health system under the leadership of Chadwick, Simon, and others, and in part to the prevailing tone of instruction in medical schools, in which preventive medicine is chiefly associated with the lectures and courses in public health. Great as is our debt to sanitary science, especially for the disappearance of many of the more striking epidemic scourges, there is an enormous amount to be accomplished in the wider field of preventive medicine, and this can only be done when the whole profession, not content with realizing its share in this duty, takes an active part in carrying it out. For the proper solution of the problem a more thorough knowledge of the etiology of disease is essential, and though bacteriology and biochemistry are clearing some of the ground, the initial symptoms and stages, the environment, and the disposing factors have as yet been imperfectly explored. In this, as Sir James Mackenzie insists, the general practitioner must play the leading part. No doubt a great deal of the work of a general practitioner is concerned with preventive medicine, but he has to rely much on his own experience and is mainly self-taught; hence, to put him in the best position to carry out this duty, he must be bred up on these lines from his earliest student days; his whole education, from the preliminary sciences onwards, should be permeated with a conception of the prevention as well as with that of the recognition and cure of disease. The replies received by the General Medical Council from thirty medical schools showed that present-day teaching

does not sufficiently meet these requirements. It appears to us that this may, to some extent, be explained as follows: As the outcome of specialization and extension of medical education, the teachers of the preliminary sciences are usually not now, as they formerly were, medical men, and the teachers of the intermediate subjects are no longer in such active touch with medical practice; their natural tendency, therefore, is to lay more stress on the principles of the science than on—what may, from their point of view, appear to be a narrower aspect—the practical bearings on the art of medicine. There is, and rightly, a revulsion against this condition of affairs, and efforts are being made to counteract the tendency to keep the medical curriculum in watertight compartments. In the United States of America this aim is being followed to an increasing degree; and although the preliminary subjects are taught before the curriculum begins, there are throughout the curriculum further courses whereby the earlier subjects are correlated with the clinical work; and in this country Professors Elliot Smith, Arthur Keith, and apparently Professor R. J. A. Berry in Australia (vide p. 75), have shown that anatomy—which unfortunately is an outstanding example of the academic method of teaching—can be made a living practical part of medicine.

After full discussion of the requirements for the teaching of the preventive aspects of medicine the Education Committee of the General Medical Council raised the question of the revision of the whole of the medical curriculum, and recommended important alterations in it, which should go some way towards producing the medical man equally able to ensure a healthy condition of the public as to cure disease when it does arise. While the minimum standard of general education required for registration is to be brought up to the level demanded in other learned professions, and the minimum age is to be raised from 16 to 17, the student should before registration have passed an examination in elementary physics and chemistry, and may receive sufficient instruction in biology to enable him to pass an examination in this subject immediately after his registration as a student. In this way the five years of the curriculum is for practical purposes prolonged, but the more complete correlation of these sciences with medicine is provided for by the recommendation of further specialized courses during the curriculum. Another important suggestion is directed at the examination bugbear which, though necessary for the sake of the weaker brethren, so often penalizes good men, and, it may be added, handicaps the teachers; this recommendation is to the effect that the record of the student's preparatory study may, at the discretion of the examiners, be taken into account in deciding the result of the examination. This is the thin end of the wedge, and it may reasonably be expected that experience will justify, as a further step in the same direction, the regular inclusion of marks, allotted on a report of the student's work, in the mark sheet of the examination.

In the third part of the article, published this week, some account is given of the views expressed by the General Medical Council and the authorities of the medical schools on the teaching of medical ethics, a matter in which the British Medical Association has taken particular interest. Many years ago an Ethical Branch was formed in Shropshire, and one result of its labours was the publication of an Ethical Code, edited by its honorary secretary, the late Dr. de Styrup. This code was very useful in its time in various ways; it was, for example, of great

assistance to this JOURNAL in its endeavour to help individual members who had become involved in disputes with colleagues or hesitated as to the course of conduct they should pursue in special circumstances. Later on, a former Chairman of the Council of the British Medical Association and member of the General Medical Council, the late Dr. Saundby of Birmingham, gave a great deal of attention to the subject, and eventually published a book, *Medical Ethics*, which was of very considerable service to the profession. Later the continuance of the publication of advice in the JOURNAL was rendered superfluous by the setting up of the Central Ethical Committee to deal with questions and difficulties of this kind. It is, of course, true that the principles of medical ethics are identical with those recognized by other professions, but they are applied to a special set of circumstances which, moreover, are of common occurrence in an almost identical setting. There are therefore certain general principles more or less peculiar to medicine which can be taught to medical students. The realization of these facts led the British Medical Association as long ago as 1905 to suggest to the authorities of the medical schools the desirability of arranging for a short course of lectures every year on medical ethics, drawing the attention of students to the principles on which it is founded. It had been proposed recently to repeat this suggestion, but in view of the action taken by the General Medical Council this is now considered superfluous.

LETHARGIC ENCEPHALITIS.

LETHARGIC ENCEPHALITIS, both in its clinical and pathological aspects, has recently been the subject of discussion in our columns on more than one occasion. We have endeavoured at various times to show that the increasing multiplicity of clinical types described does not make for any clearer appreciation of the problems presented by this disease. Special reference has been made in these columns to the recent work of French observers and to the discussions in the Académie de Médecine in Paris during which currency was given to the term "lethargic encephalitis." When M. Netter first dealt with the matter, just a year ago, he laid it down that the cardinal symptoms were fever, somnolence, and diplopia, followed by temporary paralysis of accommodation. The term "lethargic" seemed then appropriate, but recent experience has shown it to be misleading. Pathologically the disease seems to be an acute infiltrative encephalo-myelitis, due, if we may accept recent researches in New York and Paris, to a filtrable virus which can be cultivated by Noguchi's method.

Walshe,¹ in a recent paper in *Brain*, has presented a valuable study of the symptom-complexes of the disease, and in our view rightly deprecates a purely symptomatic classification, which is likely to reach quite unwieldy proportions. Following the teaching of Hughlings Jackson he would distinguish clearly between "positive" and "negative" symptoms, "positive symptoms being the expression of exalted function either from irritation or from loss of higher control, and negative symptoms expressing depression or loss of function from destruction of nervous tissue or otherwise." The symptoms, then, of lethargic encephalitis may be classified into two groups: (a) general, or signs of toxic infection, and (b) nervous, these being further divided into general and focal. The nervous symptoms may be either positive or negative. Thus, for example, lethargy or coma and paralyses are

negative symptoms, involuntary movements positive. On this basis of classification the earlier cases described—and, indeed, the classical picture—may justly be recorded as essentially negative, for the principal symptoms were lethargy and ocular paralyses.

More recently, however, positive symptoms have figured with greater prominence in the symptomatology of the reported cases. Of this group of positive symptoms myoclonus has attracted much attention. Originally described by Sicard, this particular syndrome has lately been reported with increasing frequency, though, as Walshe states, many different types of involuntary movements have been included under the name of myoclonus. An interesting feature of this group has been the combination of severe neuralgic pains with the myoclonus. Seven new cases are reported by Walshe, each exemplifying a different clinical type of the disease. The description of these cases alone shows the futility of establishing a permanent classification of the disease on a purely symptomatic basis. We have nothing but praise for this exposition of the clinical aspects of lethargic encephalitis.

From reports lately published, both in the medical and lay press, it seems probable that we may expect a recrudescence of the disease. This article in *Brain*, therefore, comes at a peculiarly opportune moment. Wilfred Harris, to whose clinical acumen we owe one of the earliest reports on the appearance of this disease in recent times, has already written to warn our readers of the possibility of such a recurrence.²

We may add a word of warning on the numerous possibilities of diagnostic error which are offered by this protean disease. In every case the most scrupulous care should be taken to exclude the presence of other inflammatory or vascular diseases of the central nervous system, and the more so since as yet no specific treatment for lethargic encephalitis exists, while valuable remedial agents are to hand in such conditions as syphilis of the nervous system or cerebro-spinal fever. Knowledge as to the probability of eventual recovery is still very inadequate. There must be by now in the country sufficient clinical material on which a real inquiry into this very important point could be instituted. We would like to suggest this as a field of study to future observers. The occasional occurrence of relapses, again, is another important point on which more information is desired. Should this country be so unfortunate as to experience another epidemic of lethargic encephalitis it is to be hoped that a concerted effort will be made to collect all the available information—epidemiological, clinical, and pathological—so that definite conclusions may be reached.

ANNUAL MEETING AT NEWCASTLE: PATHOLOGICAL MUSEUM.

THE Committee appointed to organize the Pathological Museum in connexion with the Annual Meeting of the British Medical Association at Newcastle-on-Tyne in July, 1921, proposes to arrange the material under the following heads: (1) Exhibits bearing on discussions and papers to the various Sections. (2) Specimens and illustrations relating to any recent research work. (3) Instruments relating to clinical diagnosis and pathological investigation. (4) Individual specimens of special interest or a series illustrating some special subject. It is proposed to gather together a series of exhibits illustrating the pathology of individual cases. Such exhibits will include a brief clinical history of the case and mounted

¹ Walshe, *Brain*, vol. xliii, Part III, 1920.

² Wilfred Harris: *BRITISH MEDICAL JOURNAL*, 1921, i. 47.

specimens of the different organs and tissues illustrating the pathological changes and the correlation of the lesions. Other interesting specimens will be welcomed. The chairman of the Pathological Museum Committee is Professor Stuart McDonald and the Honorary Secretary is Dr. A. F. Bernard Shaw, Pathological Department, College of Medicine, Newcastle-upon-Tyne. The museum will occupy a central position in the same building as that in which the Sectional work is carried on, and will be easy of access. Every care will be taken of specimens, and the contents of the museum will be insured. It is hoped to make arrangements for exhibitors to demonstrate their specimens.

EXPERIMENTAL INFLUENZAL INFECTION.

In the course of an extended research into experimental pneumonia F. G. Blake and R. L. Cecil,¹ working in the bacteriological laboratories of the Army Medical School, Washington, have obtained results bearing directly on the pathogenicity of the influenza bacillus. Hitherto most of the animal experiments have consisted in subcutaneous, intraperitoneal, or intravenous injection of the influenza bacillus, and attempts to produce infection via the respiratory tract have usually failed. As there is no satisfactory method of distinguishing saprophytic from pathogenic varieties of the Gram-negative haemophilic bacilli to which the name *Bacillus influenzae* is at present indiscriminately applied, a strain isolated from an empyema was used for injection into the upper respiratory passages and intratracheally into the lung. But as preliminary intratracheal injection of a monkey failed to produce any evidence of infection, the virulence of the strain was raised by successive passage through white mice and monkeys; further, on account of the extraordinary rapidity with which the *Bacillus influenzae* may lose its virulence when subcultured outside the body, special efforts were made to inoculate the respiratory passages and lungs of monkeys with cultures obtained with as little delay as possible from the passage monkeys. Twelve monkeys received applications of these cultures on the mucous membranes of the nose and mouth, and manifested an acute infection, with profound prostration, absence of leucocytosis or leucopenia, essentially similar in clinical respects to human influenza; 5 monkeys developed acute suppurative inflammation of one or both antra, and 2 monkeys bronchopneumonia yielding a pure culture of the influenza bacillus. The application of the culture medium, from which the influenza bacilli grown in it had been separated by centrifugalization, to the oral and nasal mucosa of a monkey failed to produce any toxic effects. Ten monkeys received intratracheal injections of these cultures of enhanced virulence, and 7 developed bronchopneumonia, 2 tracheo-bronchitis, and 1 resisted infection. The bronchopneumonic lungs from 3 of the 7 monkeys gave pure cultures of *B. influenzae*, and in the other 4 cultures were sterile, showing that the infection had died out. From a minute study of the morbid changes it appears that experimental influenza and bronchopneumonia resemble influenza and influenzal bronchopneumonia in man. The morbid lesions—intense engorgement, haemorrhage, oedema, purulent bronchiolitis, scattered patches of peribronchiolar consolidation and the resulting emphysema and bronchiectasis—described by W. G. MacCallum and Wolbach in man, are paralleled by those found in the experimental monkeys; but the lesions are less severe than in the human cases, as indeed might be expected in view of the great severity of the epidemic and the probable exceptional virulence of the influenza bacillus at that time. There is a difference in the pathogenesis of influenzal lung lesions, whether spontaneous or experimental, on the one hand, and those due to the pneumococcus and the streptococcus on the other hand; the pneumococcus and *Streptococcus haemolyticus* cannot initiate an infection of the normal mucosa of the

upper respiratory tract in monkeys, but they penetrate the bronchial mucous membrane at once and spread rapidly through the perivascular lymph spaces to the alveolar walls in all parts of the lobe of the lung. The influenza bacillus has not this invasive power, is rarely found in the lymphatics, blood, or interstitial tissues, and causes focal lesions by extending by continuity along the bronchial tubes. Well marked hyperplasia of the thymus was found in monkeys with *B. influenzae* infection, the gland being enlarged, firm, and with a peculiar pinkish-yellow flesh-like appearance. This condition, which has not been recognized in human influenza, appears to be merely part of a general hyperplasia of the lymphoid structures in the cervical and thoracic regions.

BLACKWATER FEVER.

PROFESSOR L. S. DUDGEON's study of 100 cases of blackwater fever in the Balkans during the years 1916-18¹ is rich in the observations of an experienced pathologist, and contains interesting criticisms of the hypotheses suggested for the solution of the vexed question of its pathogeny. Turning first to the aspects of clinical pathology: jaundice was present in 20 out of the 49 cases with full notes; some of the remaining cases had a yellowish discoloration of the conjunctiva, like that seen in pernicious anaemia, but examination of the blood plasma or serum did not show the presence of bile pigment. Emphasis is therefore laid on the importance of checking clinical impressions by laboratory tests, and a method consisting of evaporation of the blood to a dry sticky residue and then applying Gmelin's fuming nitric acid test for bile pigment is described. Numerous observations proved that the red blood corpuscles are not unduly fragile, and that the blood does not contain auto- or iso-haemolysins; on the other hand, an active haemolytic substance or substances can be extracted by alcohol or acetone from the tissues of fatal cases, and to a lesser extent from the urine, but cannot be obtained from the tissues in other conditions, including malaria. These extracts haemolyze human and animal red cells, but the urine from cases of blackwater fever does not haemolyze the red cells of man or sheep, and its injection into rabbits did not produce any bad effects. In connexion with these observations reference is appropriately made to Dr. Andrew Balfour's ingenious suggestion that blackwater fever may be due to the action of a haemolysin—introduced by a biting insect—on red blood corpuscles already enfeebled in some way, usually by malaria, but sometimes by tick fever. A malarial history was forthcoming in all the 100 cases, and it is shown that blackwater fever is at its height at the period of the year when the death rate from malaria is lowest. Film preparations of the blood during the paroxysm of blackwater fever were made in 40 of the 100 cases, and in 42 per cent. of these there were malarial parasites present, 60 per cent. of these being malignant rings or crescents. Spirochaetes were never detected in the blood or urine; and the experience with the Wassermann reaction and microscopic examination of the tissues after death did not lend any support to the view that syphilis, which is causally related to paroxysmal haemoglobinuria, plays any part in the etiology of blackwater fever. The well known hypothesis that quinine poisoning explains the disease was investigated in several ways, but neither consideration of the clinical history in the cases specially analysed from this point of view nor some animal experiments provided any evidence in its favour. Thus, rabbits rendered intensely anaemic by the intravenous injection of immune anti-serums did not show haemoglobinaemia or haemoglobinuria when treated with various preparations of quinine intravenously or intramuscularly; and complete ligature of the ureters in rabbits while quinine was being given or had been given did not induce a condition in any way

¹ F. G. Blake and R. L. Cecil: *Journ. Exper. Med.*, Baltimore, 1920, xxxii, 691-744.

¹ L. S. Dudgeon, *Journ. Hyg.*, Cambridge, 1920, xix, 203-241

resembling blackwater fever. As long ago as 1909 Cleland suggested that blackwater fever was the evidence of anaphylaxis to the dead protein of the malarial parasite, and since then this idea has attracted some attention; but from a comparison of the morbid changes in blackwater fever with those in two fatal cases of anaphylaxis, Professor Dudgeon concludes that the only phenomenon common to both is the haemorrhagic state, which, of course, may be due to various causes.

INFECTIOUS MONONUCLEOSIS.

Writing from the division of clinical pathology of the medical clinic in the Johns Hopkins University and Hospital, T. P. Sprunt and F. A. Evans¹ describe, under the somewhat laboratory title of mononuclear leucocytosis in relation to acute infections ("infectious mononucleosis"), a fairly clear-cut clinical group of cases, whether or not they may eventually prove to be all due to the same cause. These cases are of interest inasmuch as they may be regarded as acute leukaemia or lymphadenoma, and, though the authors do not refer to this point, have very probably been described under the name of glandular fever. Six cases, all in young adults, are reported; all had enlarged and tender cervical glands and five of the six had in addition a similar condition in the axillae and groins; the spleen was palpably enlarged in four. The average duration of fever was between two and three weeks, and was accompanied by moderately severe prostration. One patient had albumin and casts in the urine. In four of the cases there was tonsillitis or pharyngitis. The total leucocyte count was normal at first, but later there was a leucocytosis of 13,000 to 20,000 per cubic millimetre; the differential count showed a slight increase in the cells of the large mononuclear transitional group and the presence of many pathological lymphoid forms; later again there was a leucocytosis largely due to lymphoid cells, many of which were pathological. In three cases kept under observation these blood changes were found to persist for some weeks after the signs and symptoms had disappeared and then to pass away. The red blood cells, haemoglobin determinations, and the platelets, did not show any alteration other than that of a mild secondary anaemia incident to an acute infection. The prognosis, as shown by these six cases, which all recovered, appears to be good, but it is interesting to note that "eminent haematologists have considered the possibility of a leukaemia of transient nature from which the patient recovers spontaneously." Sections of excised glands were not normal, the lymphocytes being increased in numbers, but no positive diagnosis was justified. Attempts to determine the infective agent were unsuccessful; the Wassermann reaction and blood cultures were negative, and animal inoculation of a gland in one case did not give any information. In 1913 R. C. Cabot drew attention to the occurrence in rare instances of a lymphocytosis in wound sepsis, boils, and streptococcal adenitis of tonsillar origin, which can be distinguished from lymphoid leukaemia by the recognition of an infective origin for the adenitis, the lesser degree of the infective lymphocytosis, and the course of the disease. Professor Arthur Hill in the same year recorded such "a case resembling acute lymphatic leukaemia ending in complete recovery," and similar examples have been reported by Lüdka, Marchand, Sanders, and by Turk, who considered these cases as a key to the etiology of acute leukaemia.

PROFESSOR EDWARD HILL OF DUBLIN.

Among the attractions of the study of medical history it is not impossible that there may lurk a gratifying feeling of self-congratulation on our superior or more fortunate conditions as compared with those of our professional forebears. Thus, in tracing the development of a school of medicine, or in recording the evolution of medical science,

we can from our secure pinnacle graciously award praise to those who struggled with difficulties that no longer block our way. A century ago medical controversies were conducted with the same violence of language and imputation of motives as those in which politicians and writers habitually indulged. How far the change in manners is superficial and a phase of fashion and how much may be ascribed to a real change in human nature will be variously estimated by each one of us according to his experience and temperament. That medical polemics flourished in Dublin as well as elsewhere is shown by the interesting sketch of Dr. Edward Hill (1741-1830) drawn by the scholarly Registrar of the Royal College of Physicians of Ireland, Dr. T. Percy C. Kirkpatrick, and presented by him to the College on St. Luke's Day, 1920. Dr. Edward Hill was for forty-nine years Regius Professor in the University of Dublin, and held every office, including that of president on five different occasions, and finally, when in his seventy-ninth year, became Dun's librarian in the Royal College of Physicians of Ireland. He was an accomplished scholar, well acquainted with the Latin, Greek, French, and Italian classics, and possessed of considerable skill in architecture; but he did not leave any medical writings, and does not appear to have been very fond of hospital practice, which he described as "a dangerous and arduous duty." What he regarded as his life's work was a word-index of *Paradise Lost*—containing references to every occurrence of even the words "the," "and," "as"—which never saw the light of day, and may well be remembered as a monument of misdirected energy. His views about the duties of a teacher were formal to a degree: provided that a student knew his Hippocrates, his Galen, and his Celsus, what need had he to study sick people? It is not surprising that the Regius Professor was firmly opposed to the new-fangled idea, put forward about 1811 by James Macartney, Professor of Anatomy, that examinations held under the *Licet ad examinandum* should be conducted in English instead of in Latin. But the most striking feature of Hill's long professional and professorial life is the weary and acrimonious disputes in which he was constantly engaged, mainly with Percival. This rather unscrupulous rival had studied in Edinburgh and on the Continent, and was deeply impressed with the importance of clinical instruction; but his chief object appears to have been selfish, for he desired to be in a position to pose as the founder of a great hospital in Dublin. In this he partially succeeded, for the west wing of the present Sir Patrick Dun's Hospital in Great Canal Street was opened in 1807, but Percival's name is scarcely remembered in the institution for the foundation of which he sacrificed so much honour. Hill, who wrote "in a baneful hour the utility of clinical lectures was suggested," failed in his opposition, but his honour remained untarnished. The truth is that both the antagonists, while professing to work for the good of the school, also strove for their personal aims.

MEMORIAL TO THE LATE DR. A. J. CHALMERS.

THE late Dr. A. J. Chalmers—the well-known authority on tropical diseases, and joint author with Dr. Castellani of *Tropical Medicine*—whose sudden death on his way home on leave in April last shocked the profession and his numerous friends, left a splendid collection of medical books mainly on tropical diseases, and including some almost priceless incunabula. The whole of these, with the exception of about sixty volumes, presented to the Royal College of Physicians of London, have been presented by Mrs. Chalmers to the Royal Society of Medicine, which has decided that the collection shall be kept together and be known as the "Chalmers Collection." Mrs. Chalmers, we are informed, has presented the society with the sum of £500 for the shelving and furnishing of a room in which the books will be kept as a memorial of her husband. It is hoped that the collection of books on tropical medicine

¹ T. P. Sprunt and F. A. Evans, *Bull. Johns Hopkins Hosp.*, Baltimore, 1920, xxvi, 410-417.

will be added to from time to time, and the room chosen for the Chalmers Library is well adapted for the purpose. This coincides with the reconstruction of the new Section of Tropical Medicine and Parasitology. The Section was formed in 1912, but was suspended during the war, and has only this session been formally constituted, and among the first nominated officers are Lieut.-Colonel Sir Leonard Rogers, I.M.S., as president, and as vice-presidents, Professor Leonard S. Dudgeon, Lieut.-General Sir John Goodwin, D.G., A.M.S., Vice Admiral Sir Robert Hill, D.G.M.S., R.N., and Professor G. H. F. Nuttall. The new Section is fortunate in being able to start with a library of its own—perhaps the finest collection of books on tropical medicine to be found anywhere.

THE ROYAL CHEST HOSPITAL.

A SPECIAL meeting of the governors of the Royal Chest Hospital, presided over by the Lord Mayor of London, will be held at the Mansion House on Monday next, at 3 p.m., to consider and, if thought fit, to approve the scheme for the amalgamation of the Royal Chest Hospital, City Road, with the Great Northern Central Hospital. The suggested scheme is for the provision by the Great Northern Central Hospital of a number of beds allocated to diseases of the heart and lungs at least equal to those given up by the Royal Chest Hospital; the present buildings in City Road are to remain as the Royal Chest Section of the Great Northern Central Hospital until such time as building becomes practicable, when a block in the reconstructed Great Northern Hospital is to be named "The Royal Chest Hospital Block," and the out-patient department of the Royal Chest Hospital will continue in the City Road as an outpost of the chest section of the Great Northern Central Hospital; proper provision is to be made for both lay staff and medical staff of the Royal Chest Hospital. The Minister of Health was invited to express his opinion on the arrangements for amalgamation, and had no modification to suggest, agreeing that it would be wiser to amalgamate now, while the Royal Chest Hospital was free of debt, since its council had come to the conclusion that it could no longer undertake the responsibility of raising funds.

THE ALEXANDER AND PARKES MEMORIAL PRIZES.

THE Alexander Memorial Prize, consisting of £50 with a gold medal, is awarded every third year to the writer of the best essay on a subject dealing with military surgery, military medicine, or military hygiene. The competition is open to executive officers of the R.A.M.C. on full pay, with the exception of professors and assistant professors of the Royal Army Medical College. The subject for the next prize is "Trench foot: its pathology and treatment (medical and surgical), with the administrative measures for the reduction of its incidence." Essays must bear evidence of the personal observations and experience of the writers; they should be sent to the Secretary, Alexander Memorial Prize, at the Royal Army Medical College, Millbank, S.W.1, by December 31st, 1921; each essay must have a motto, and be accompanied with a sealed envelope bearing the same motto, and containing the name of the competitor. The Parkes Memorial Prize, consisting of seventy-five guineas in money, with a gold medal of the value of fifteen guineas, is awarded every third year to the writer of the best essay on a subject connected with hygiene. The competition is open to the medical officers of the Army, Navy, and Indian Services, of executive rank on full pay, with the exception of the professors and assistant professors of the Royal Naval Medical College, Greenwich, and of the Army Medical School during their term of office. The subject for the next prize is "The means of spread and method of control of bacillary dysentery in the field" (to be illustrated, so far as practicable, from the personal experience of the writer).

Essays should be sent to the Secretary, Parkes Memorial Fund, Royal Army Medical College, Millbank, by December 31st, 1921. The rule as to the use of mottoes applies to this prize also.

REGULATIONS UNDER THE DANGEROUS DRUGS ACT.

THE Home Secretary, under the Dangerous Drugs Act, 1920, has drafted regulations for controlling and restricting the possession, sale, and distribution of raw opium; and a further set of regulations for controlling the manufacture, sale, possession, and distribution of morphine, cocaine, ecgonine, and diamorphine (commonly known as heroin) and their respective salts, and medicinal opium, and preparations and substances containing not less than one-fifth per cent. of morphine or one-tenth per cent. of cocaine, ecgonine, or diamorphine. Generally speaking these drugs may be supplied only to persons specially authorized, except when lawfully dispensed from a prescription given by a qualified medical practitioner in accordance with specified conditions. Persons, including medical practitioners, who dispense such prescriptions, must keep separate books for records of all dealings in the four groups of drugs: (a) cocaine and ecgonine and substances containing them; (b) morphine and substances containing it; (c) diamorphine and substances containing it; (d) medicinal opium. Medical practitioners and registered dentists and veterinary surgeons, together with dispensers at public hospitals or institutions registered under the Pharmacy Act, 1868, may possess and supply these drugs, so far as is necessary for the practice of their profession or employment. We propose to refer to the draft regulations in more detail at a later date. They appear to be in line with the war-time restrictions, introduced under the Defence of the Realm Act, which were described in our issue of November 17th, 1917, at p. 657.

HOSPITAL INQUIRY COMMITTEE.

BETWEEN the rejection of the Ministry of Health (Miscellaneous Provisions) Bill in the House of Lords on December 14th, 1920, it was urged upon the Minister of Health by members of both Houses that every effort ought to be made to sustain the voluntary hospital system. With this object in view Dr. Addison agreed to appoint a small independent committee to consider the financial position of voluntary hospitals throughout the country and to make recommendations thereon at an early date. No official announcement has yet been made regarding the membership of this Committee, but a statement has appeared this week, and it is understood to be well founded, that the chairman will be Viscount Cave, who was Home Secretary from 1916 to 1919. The intention is that the Committee shall consist of five, and it is probable that the members will include Sir Clarendon Hyde, who is associated with Lord Cowdray as a director in a number of his undertakings.

IN the *London Gazette* of January 11th it was announced that the King has signified his intention of conferring the honour of knighthood upon Dr. Maurice Craig, C.B.E., and Dr. P. Horton-Smith Hartley, C.V.O. Sir Maurice Craig is physician for psychological medicine and lecturer in the same subject at Guy's Hospital, and consulting neurologist to the Ministry of Pensions. Sir Percival Horton-Smith Hartley is physician and joint lecturer in medicine at St. Bartholomew's Hospital, and senior physician to the Brompton Hospital for Consumption.

IN England sanatorium benefit will cease on May 1st to be included among the benefits conferred on insured persons by Part I of the National Insurance Act, 1911; in Scotland this termination has already taken place, and as from January 1st, 1921, the Public Health Local Authorities have been required to make arrangements for the treatment of tuberculosis in insured persons.

India.

CALCUTTA SCHOOL OF TROPICAL MEDICINE.

It is rather more than ten years since Sir Leonard Rogers proposed that a fully staffed and properly equipped school of tropical medicine should be founded in Calcutta. The proposal was approved by the Government of India, and an endowment fund was opened in 1914. It received liberal support from Indian noblemen, from the tea, jute, and mining associations, from the Tata oil and iron companies, and from Sir David Yule, who endowed a European chair of research in biochemistry; when Sir Leonard Rogers left India early this year he had the satisfaction of knowing that the whole scheme was on the way to completion. An appeal has recently been issued for further contributions to complete the endowment and equipment. The Calcutta School of Tropical Medicine and Hygiene consists of the school proper with its laboratories, an institute of hygiene with its laboratories, under the same roof as the college, and the Carmichael Hospital for Tropical Diseases with 116 beds. It is not intended that the classes at the school should exceed about forty, and the lecture theatre has been designed to accommodate fifty. The school building has four stories, and the laboratories have been designed under the supervision of Sir Leonard Rogers for the special purposes they are intended to serve. On the second floor is a temperate laboratory built with double windows and insulated walls, so that its temperature will be constantly below 70 F.; this will allow protozoological research work requiring low temperatures to be carried out at all times of the year. The fourth floor contains a series of eight laboratories for research work, an animal room, a dark room, and microphotographic apparatus.

The purpose of establishing the hygiene section is to combine in one building laboratories under the control of the Sanitary Commissioner of Bengal, to co-ordinate the public health laboratory work of the province, and to raise the standard of education and efficiency of Deputy Sanitary Commissioners by providing facilities for post graduate teaching and research. Classes for the degree of bachelor of hygiene and the diploma of public health of Calcutta University will be held annually from October to June.

The Carmichael Hospital is to be conducted as part of the tropical school. The hospital, which is close to the school, will be administered by the director of the school, who will allot beds as required to the members of the staff. The number of beds is 116 (43 European and 73 Indian), and the staff, which consists of eight professors and seven research workers, is large enough to ensure the intensive study of selected cases and personal teaching. There is a clinical laboratory.

The appeal now made is for contributions towards the upkeep of this hospital, to increase the endowment for a whole time chair in research work, to endow an Indian research scholarship, and for improved equipment. Contributions are also asked to enable the chair of entomology and helminthology to be divided; it is regarded as very desirable to have a chair of helminthology in a country such as India, where helminthic infestations are very common. The director of the school is also professor of tropical medicine. The other chairs are tropical pathology and bacteriology, pharmacology, serology and immunology, tropical hygiene, biochemistry, and protozoology. The school has also a research chemist and teacher of chemistry and physics, and the hospital a resident medical officer. The members of the professorial research staff will devote their whole time to teaching and research, and will be deburred from private or consultant practice, receiving a local allowance in lieu. In order to maintain the standard necessary for post-graduate teaching it is proposed that all professorial and assistant professorial appointments shall be made by the Government of India, so that there may be the freest possible scope for the selection of the best men available in India.

MEDICAL COLLEGES IN BENGAL.

The Governor of Bengal, Lord Ronaldshay, who presided at the annual prize distribution at the Calcutta Medical College on December 1st, 1920, said that the rapidly increasing demand for medical education in Bengal was a most striking fact. This year the number of applicants for admission

to the Calcutta Medical College was 947, largely exceeding the number of vacancies, which was 153. The Government was anxious to increase facilities throughout the Presidency. To add to the efficiency of the Calcutta College heavy expenditure had been incurred, including the acquisition of plots of land at a cost of 21½ lakhs; the expenditure on servants' quarters was over 5 lakhs. It was intended to make provision also for students' hostels. Since Lord Ronaldshay spoke it has been officially announced that to meet the demand for a greater number of qualified medical practitioners the sanctioned strength of students at the Calcutta Medical School has been raised to 500 and at the Dacca School to 400. A medical school, with accommodation for 203 students, will be opened at Bardwan, and the question of establishing medical schools in other centres is under consideration, as are also schemes for the establishment of hospitals for incurables and convalescents in Calcutta, and for a leper colony.

England and Wales.

WORK OF THE CENTRAL MIDWIVES BOARD.

In the annual report on the work of the Central Midwives Board the number of midwives on the roll is given as 45,960, a net increase for the year of 1,794. Of these, the number (so far as can be ascertained) who actually practise as midwives is relatively small, being only 11,488, of whom 7,865, or 68.5 per cent., are trained, and 3,623, or 31.5 per cent., untrained. The number of candidates entering for the Board's examinations during the year was 2,391, as against 1,937 in the previous year, and of those who completed the examination 1,934 passed, the percentage of failure being 18.8. Of the 54 penal cases dealt with by the Board, 22 were those of women who had neglected to advise medical assistance in cases of ophthalmia neonatorum, this large percentage being due, no doubt, to more vigilant action on the part of some of the local supervising authorities. At a conference of the Board with the Ministry of Health and the Board of Education it was agreed:

1. That as far as the training of pupil midwives was concerned a maternity home could not safely be combined with an infectious diseases hospital unless the wards of each were entirely separate, and the staff, both medical and nursing, were unable to meet.
2. (a) That where a maternity home was combined with a general or Poor Law hospital, an isolation block or ward should be set apart, and one or more nurses told off to attend the cases as they arose, and that the nurses should attend such cases only. (b) That while working in the maternity wards no pupil should be employed in any other work.
3. That a maternity home should not be recognized for the purpose of training pupils until it was able to show (a) that it had an adequate staff and arrangements for training, and (b) that it had a suitable number of cases to train upon.

MATERNITY HOMES AND CHILDREN'S INSTITUTIONS.

A memorandum has been issued by the Ministry of Health asking for information to be furnished annually by the authorities of maternity homes and hospitals for each year ending December 31st. This information should include: the total number of cases admitted; average duration of stay; number of cases (a) delivered by midwives, (b) by doctors, (c) in which medical assistance was sought by midwives, with reasons; number of cases notified as puerperal sepsis, and the treatment thereof; number of cases in which temperature rose above 100.4° for twenty-four hours, and pulse rate in such cases; number of cases notified as ophthalmia neonatorum, with result of treatment; number of cases of "inflammation of the eyes, however slight"; number of infants not entirely breast-fed while in the institution, with reasons; number of maternal deaths, with causes; number of foetal deaths (stillborn or within ten days of birth), with causes thereof, and results of post-mortem examination if obtainable. Immediate information should be sent to the Ministry of every case of maternal mortality occurring in the institution or due to illness contracted there, and of every notified case of puerperal fever.

The Ministry of Health has issued also a memorandum asking for annual information, to be supplied for the year ending December 31st, by the authorities of institutions

receiving resident children under 5 years of age. The desired information includes number of cases admitted, average duration of stay, reasons for admission, number and condition of health of cases discharged, number of cases of infectious disease, number of deaths with causes thereof, and number of children discharged on account of illness. It is further desired that immediate information should be sent to the Ministry of all deaths from gastro-enteritis or epidemic diarrhoea, with a brief statement of the circumstances.

Ireland.

ROBERT CAMPBELL MEMORIAL.

THE following additional subscriptions have been received towards the memorial to commemorate the pioneer work done for surgery by the late Mr. Robert Campbell of Belfast. It is proposed to establish a prize for distinguished work in any branch of medical science done by a member of the medical profession in Ulster or a graduate of Queen's University, Belfast.

Correspondence.

THE VOLUNTARY PRINCIPLE AND THE BRADFORD BOGEY.

SIR,—Amidst all the turmoil and discussion about the future of the hospitals Bradford is always being brought forward, first of all as an example of the failure of the voluntary principle, and secondly, as an example of what will be done for the salvation of the sick poor when once our hospital requirements are put into the hands of our municipal authorities.

May I, once and for all, put it on record that nearly everything which has been said about Bradford up to the present time is "more or less untrue"? Certainly nothing is more untrue than the statement that no poor patient can obtain admission to the Royal Infirmary unless he pays a fee to a member of the honorary staff. Such a statement has been made, and has found its way to the Ministry of Health, and has apparently been accepted in good faith. What an acknowledgement for four years' strenuous and gratuitous war service on the part of the honorary staff!

From your report of the recent conference on hospital finance it appears that Dr. Peter Macdonald of York repeated the Bradford story which has been current for a long time past—a story which is just so much propaganda to promote a general socialistic hospital policy throughout the kingdom. Lest his remarks should be accepted as those of an authority because they have not been challenged, will you allow me to analyse them?

Dr. Macdonald stated in the first place that we have 361 beds for a population "which cannot be less than half a million." The last record of the Bradford population was nearly approaching three hundred thousand. His estimate of the available hospital accommodation in the city, may I point out that within a circle of twenty miles radius there are something like a score of hospitals which unite in providing hospital treatment for this part of the West Riding?

As regards Bradford itself, Dr. Macdonald states that "the conditions are so intolerable" that a municipal hospital has been established. That statement is incorrect. What has happened is that the guardians have recently handed over the management of the Poor Law hospital to the Health Committee of the Bradford Corporation, and the Poor Law hospital has thereby become

a municipal hospital. In spite of the change of name it remains the same old obsolete group of buildings which the Local Government Board condemned as unfit for hospital purposes twenty years ago. Moreover, it has been admitted at a town council meeting that after allowing for all the accommodation earmarked for what may be called public health purposes there is nothing left for general surgery and medicine. Nevertheless, the socialistic and Labour party, prior to the recent municipal elections, made haste to announce that they had now acquired a hospital second to none in the country and equipped with every modern convenience for dealing with all surgical and medical cases. The voluntary institutions were "back numbers" and would be scrapped, and everything would be on the rates before long.

Now, Sir, I have spent twenty years in Bradford, and during that period I have treated at least ten thousand working-class patients in the Royal Infirmary. I know that I am regarded as a "tiresome person" who is difficult to satisfy. The Royal Infirmary is an old obsolete building nearly as bad as the municipal hospital, and it is no fault of mine that we have not already acquired a new building. Nevertheless, we treat three thousand patients a year, and our results compare most favourably with any of the neighbouring cities, not excepting our great neighbour Leeds. There has been a great outcry about waiting lists, and we have been treated to a pathetic picture of the sick poor, hoping against hope for a long-delayed relief. During the war there was great hardship. Which of us had not to endure it? To-day there is no waiting list at the Royal Infirmary beyond a few patients who have fixed a certain date for admission to suit their own convenience.

Dr. Macdonald, whom I remember in Bradford some twenty years ago, has been talking "through his hat." He suggests that the Royal Infirmary is bankrupt to the tune of £1,000 a month. As a medical man he has forgotten or never learnt the axiom of one of our greatest surgical teachers, "Never believe anything you hear and only half of what you see"! In 1914 the income and expenditure of the Royal Infirmary balanced. Since that date, during a period of seven years, we have incurred a debit of £22,000. In 1914 our annual subscriptions, apart from investments and donations, amounted to £6,000. The workpeople's fund realized £3,400 in addition. The annual subscription list for 1920 is not far short of £17,000. The workpeople's fund is something over £9,000. We have received a cheque for £10,000 from the National Relief Fund against our overdraft. We have paid for a site for a new infirmary worth £20,000 and have £35,000 in hand besides promises for another £20,000. In addition we have just received £23,000 for a new infirmary from the old war hospital account! Moreover we have wiped out the socialistic party on the town council!

I trust that before the conference meets again, Dr. Peter Macdonald will have pondered over these facts, and taken them to heart. I trust that I shall not be considered as an extreme enthusiast for the voluntary principle. I should welcome a change of the old system, but I will fight to the last a policy which involves the murder of the voluntary hospital, and puts everything on the rates. We want co-operation. A first-class general infirmary and a municipal hospital to work with it is the ideal. The latter should be staffed by the younger men who are aspiring to establish themselves as the consultants of the city; as soon as they acquire an honorary appointment on the voluntary hospital they should relinquish the salaried appointments at the municipal hospital and "take silk." Such an arrangement would be a blessing to everyone concerned.—I am, etc.,

Bradford, Jan. 5th.

J. BASIL HALL.

VOLUNTARY HOSPITAL STAFFS.

SIR,—Why does the medical profession desire to do the staffing of hospitals without remuneration? Such is the question put by Dr. Rees to the medical profession in your last issue. As I have been interested in the subject for many years, may I offer a partial answer, though I am unable to answer it completely?

In 1839, when the question of provision of hospital accommodation for the working people was considered by the Poor Law Commissioners, the members of the staffs of the metropolitan medical schools attached to charity

hospitals came to the conclusion that, were the State to establish hospitals in addition to the "charity" hospitals then in existence, they, as teachers, would be deprived of clinical cases necessary for the instruction of their pupils—the pupils being indirectly their source of future income. To-day the reason is ostensibly perhaps no longer quite the same, but the staffs of charity hospitals—in name—will in all probability join together with an object identical with that of the doctors who opposed the Poor Law reform in Victorian years, but the purpose now, as then, is essentially to prevent change, and to retain existing privileges.

Many members of the staffs of hospitals, with and without medical schools attached, now receive payments for the services they render, and they do this under the cloak of the title of honorary officer. I would ask, as a corollary to Dr. Rice's question, is this a course that can be justified?—I am, etc.,

Cambridge, Jan. 10th,

JOSEPH GRIFFITHS, Colonel.

LINE OF ADVANCE IN THE SURGERY OF BREAST CANCER.

SIR,—There are one or two points in Mr. Handley's most interesting paper on lines of advance in the surgery of breast cancer which I think call for consideration.

The mode of advance of the disease has been fully described in previous communications by Mr. Handley, but in the present one he emphasizes the supraclavicular and intercostal routes.

The tables of recurrence furnished indicate the prevalence of the supraclavicular route, and this confirms my own observations, which led to careful examination in the supraclavicular area for evidence of enlarged glands, with, in many cases, negative results.

As recurrence followed in this area, and in some instances many years after the excision of the mamma, it was felt that had the supraclavicular glands been removed a greater approach to a cure would have been effected. With a view to determining the condition of the supraclavicular glands which yielded no clinical manifestations of involvement, I decided to select six cases of breast cancer in which the growth was slow, the skin involvement slight, and the axillary glands palpable. A further examination of the supraclavicular area was made while the patient was under an anæsthetic, but no enlargement of glands was made out. After the removal of the breast and the axillary glands the dissection was continued into the neck, and in order to obtain free access to the glands at the inner angle the clavicular portion of the sternomastoid muscle was divided. All the loose tissue and glands were carefully removed, and for the purpose of microscope examination the tissue on the outer half of the space was kept separate from that on the inner side. On the completion of the operation most of the structures in this space, including the scalenus anticus and the phrenic nerve, were exposed.

In all six cases the parts removed from this area were examined by myself and the pathologist, and we failed to determine in three cases by the naked eye whether the glands were involved. A microscopic examination, however, showed that in five cases the glands were the seat of carcinomatous invasion; in only one case were the glands free.

It seems to me that no operation on the breast can be regarded as complete until the state of the supraclavicular glands is determined. The proximity of these glands to the first and second intercostal spaces would to my mind suggest that the intercostal recurrence was an extension from them. In any case no one will doubt the force of the statement, "Cancer cells which have reached the supraclavicular glands have obtained a favourable strategic position for the extension of their attack in various directions."

Apparently Mr. Handley does not favour the extension of the primary operation to the supraclavicular area, and yet in an earlier part of his paper he states that "there can be no doubt that the right treatment of supraclavicular recurrence in its early stages is operative." He would wait until the glands were palpable, yet this delay might determine the involvement of the gland capsule and the infiltration of the surrounding tissue. In one of my cases referred to this had definitely taken place. The suggested alternative to operation, of the introduction of radium

into the supraclavicular area, would be difficult of attainment in the west of Scotland owing to the limited supply available. So far the extended operation has not proved a serious strain on the patient, and in the six cases I describe there has been no recurrence; it is, however, too soon to make any definite pronouncement on this point. Personally, I strongly favour removal of the glands in the supraclavicular area, even in cases where they are not clinically detectable.—I am, etc.,

Glasgow, Jan. 10th.

R. H. PARRY.

GASTRIC ULCER AND GASTRIC CANCER.

SIR,—Mr. Thurstan Holland's interesting paper in your issue of January 1st contains the following very important statement:

"The experiences of a large x-ray department are strongly opposed to the theory that it is usual for cancer of the stomach to be preceded by a simple ulcer."

It will be remembered that there appeared some years ago a series of papers professing to prove that a very high percentage—even 75 per cent. and upwards—of gastric cancers were preceded by definite clinical evidence of gastric ulcer. I pointed out at the time that this was contrary to all competent medical opinion, and that those who made such statements were dealing with such highly specialized material—chiefly gastric ulcer cases—as to make any such generalization impossible.

It is interesting to see that radiological experience is now supporting the clinical experience of observers who have to deal with all kinds of gastric cases. The error they oppose is a serious one, obscuring diagnosis and misdirecting treatment.—I am, etc.,

Exeter, Jan. 10th.

W. GORDON.

THE MINISTRY OF HEALTH AND THE PROFESSION.

SIR,—I have no wish to engage in a controversy with Dr. Fothergill, but he ought not to be allowed to misquote my letter and misrepresent its tenor without a reply. Dr. Fothergill is, of course, at liberty to summarize as much as he likes, if he does it fairly, but when he places his summary within quotation marks and gives it a separate paragraphing he does what is not legitimate. I did not write what he quotes me as having written.

His misrepresentation seems to me to be equally deliberate, for on re-reading my letter I find no ambiguity. There was no invitation to the profession to concern itself with "politics and its many underhand ways," nor to indulge in any "deliberate individual partisan action on behalf of the present Ministry of Health." I distinctly said that "the politicians concerned may be left to look after their own case." The danger to which I drew attention was an attempt "to undermine the position and machinery of the Ministry [of Health] itself, and to discredit those of our own profession who are attached to it," particularly with reference to the equality of status of the medical and lay sides of the Ministry. This has nothing to do with party politics, or with specific questions of policy at all.

The Association was largely responsible for the setting up of the Ministry of Health with its present position and machinery. We felt very strongly about it, and Dr. Fothergill gave it as large a measure of support as he ever gives to anything. Now, when an attempt, with whatever motive, is being made seriously to degrade the importance of the Ministry, to make its medical side wholly subordinate to its lay side, and to prevent the publication and proper consideration of reports on medical and health subjects of vital importance to us all, Dr. Fothergill implores us to watch unmoved the destruction of much of the work which by our united efforts we so recently accomplished. I, on the contrary, assume that the principles we enunciated were seriously held, and that we still desire a Ministry of Health as a first-class department of State, within which, and in relation to which, the medical profession shall hold a position of importance second to none. If this be so, we ought now once more to emphasize these principles and this position, and neither to fold our hands nor, with Dr. Fothergill, to jump thoughtlessly to the aid of those who wish to relegate professional influence to its previous subordination in a variety of departments.—I am, etc.,

Hornsey, N., Jan. 8th.

H. B. BRACKENBURY.

ADRENALIN IN RESUSCITATION.

SIR,—I have read the article on this subject by Dr. Cranston Walker, in your issue of January 8th, 1921, with much interest. I performed a number of experiments on this subject some twelve years ago and came to the conclusion that in adrenalin we had the most powerful agent yet discovered for resuscitating the apparently dead. I found that it was possible to revive cats that had been dead (from chloroform poisoning) as much as twenty minutes after all signs of life had ceased. In one experiment the heart was exposed and attempts at resuscitation were not begun for twenty minutes after the heart was seen to have stopped beating.

It was found that the most effectual method of using adrenalin was not by injecting into the heart, but by giving a saline infusion into the veins containing 1 in 50,000 adrenalin. This was almost invariably effective in restarting the circulation, and direct stimulation of the heart was not necessary, the heart being automatically stimulated by distension of the right auricle.

I believe it to be a most valuable method of restoring to life persons who have died suddenly from accident, but who have no vital injury, such as cases of electric shock, drowning, and chloroform poisoning. The difficulty of its application lies in the fact that the necessary person skilled in the use of adrenalin transfusion, and the necessary simple apparatus, are so seldom available when wanted.—I am, etc.,

J. P. LOCKHART-MUMFERY, F.R.C.S.

London, W., Jan. 10th.

A Disclaimer.

SIR,—I very much regret that my article "Adrenalin in Resuscitation" (printed in last week's issue, p. 46) has been quoted and misquoted in the lay press, in some cases under sensational headlines, and with free use of my name. My article was meant to be a brief and cautious note of some experiments and suggestions—a pendant to Mr. Welby Fisher's paper—possibly of interest to others working on the subject. Further publicity was never imagined, and is most regrettable. I take responsibility only for the article as printed in the BRITISH MEDICAL JOURNAL, and take no responsibility for any statement on the subject made in the lay press.—I am, etc.,

Birmingham, Jan. 11th.

CRANSTON WALKER.

GLANDULAR FEVER.

SIR,—In the *Times* of to-day's date its medical correspondent calls attention to a mysterious infection, characterized by swelling of the glands round the angle of the jaw. I think it is probable that these are instances of glandular fever, which was first described by Pfeiffer in 1889, and of which a very good account was published by Sir Dawson Williams in 1897.

Glandular fever especially attacks children, but adults are not immune. Its principal characteristic is a rapid enlargement of the cervical glands deep to the sterno-mastoid muscle, usually towards its anterior border and about the middle of its length. There may be a previous period of malaise of twelve to forty-eight hours. The enlargement is sufficient to form a marked prominence on the neck. It may be entirely painless. The axillary and inguinal glands may also be enlarged, though to a much less extent, and also other glands in the neck. The spleen becomes palpable about the fourth day in a considerable proportion of cases. The temperature is commonly 101° to 103° , but may be higher. Changes in the fauces are very slight, and tonsillitis is absent. After a few days the glands in the neck subside rapidly, and convalescence is established in the second week. There is no rash. Suppuration is very rare. Complications are rare, the most frequent being a "haemorrhagic nephritis," which is apparently transient. Anaemia may develop, and convalescence is often prolonged. The glands may be palpable, though not visible, for several months. The blood in the acute stages may show a leucocytosis of 12,000 to 15,000 per cubic millimetre with a lymphocytosis. As to diagnosis, it is distinguished below the angle of the jaw and swelling being distinctly below the angle of the jaw and by the freedom of the parotid. It is distinguished from infections of the fauces by the absence of tonsillitis and

the slight degree of changes in the pharynx. The absence of anaemia in the acute stages will rule out the diagnosis of acute leukaemia.

Treatment in the acute stages is symptomatic, but care must be taken during convalescence. The onset is usually unilateral, and the opposite side may be affected subsequently, or occasionally a recurrence takes place on the same side. I saw a typical case from its onset in July, 1920, and since then I have seen two others in hospital practice, nephritis occurring in one instance.—I am, etc.,

London, W., Jan. 5th.

H. LETHBRIDGE TIDY.

PREVENTION OF VENEREAL DISEASE.

SIR,—The opponents of immediate self-disinfection seem to object to my having recommended that all boys and girls should have access to the latest scientific knowledge of this subject.

In speaking of boys and girls, I naturally referred to those who had reached the age of puberty. I did so designedly, being mindful of the prevalence of venereal diseases among the adolescent portion of the population.—I am, your obedient servant,

London, S.W.1, Jan. 7th.

WILLOUGHBY DE BROKE.

SIR,—Having just read the letters on this matter by Mr. Wansey Bayly and Dr. Jane Hawthorne in your issue of January 1st, and, in consequence, having re-read the "Note" distributed by the Medical Women's Federation, which is the subject of the just criticism of these writers, I desire to add a few supplementary remarks.

Some weeks ago I received a copy of the "Note" in question from the Medical Women's Federation, of the existence of which body I was previously ignorant. This Note bore no further indication of its authorship. As one of the lecturers at the London School of Medicine for Women for a period of over twenty years, dating from the time before women were admitted to the *Medical Register*, I was led by perusal of this Note to the conclusion that it was merely a manifesto from an inconsiderable clique composed of members with far inferior intelligence to that possessed by the average classes to whom in past years I had the pleasure and privilege of lecturing. The authors of this document apparently lacked the courage to name the society against which they directed their farrago of erroneous and irresponsible statement. The whole of the "Note" contains nothing but expression of biased opinions with no evidential basis whatever, and of deliberate misrepresentation of the principle and practice advocated by the Society for the Prevention of Venereal Disease.

I wish to subjoin to the weighty criticisms by Mr. Bayly and Dr. Jane Hawthorne the statement that such instructions relating to the disinfection of women as were given by this society were not considered as an essential part of the method of prevention which the society advocated. They were, in fact, inserted, with certain restrictions, mainly on the somewhat insistent representations of many medical women. It is, of course, well known that really efficacious disinfection is far more difficult of achievement in the case of women than of men, whether the attempt be made by the women themselves or by others; and it is clear that successful disinfection of males must entail freedom from infection of females and their progeny.—I am, etc.,

London, W., Jan. 4th.

H. BRYAN DONKIN.

P.S.—Please allow me a short comment on one letter that appeared in your issue of January 8th, in reply to Mr. Bayly and Dr. J. Hawthorne. Dr. Otto May, while professing himself as "loath to intervene" in the discussion of this subject, intervenes without showing any cause. The statements he makes concerning "prevention" in the British army on the Rhine are unverified, contrary to those made by others who have inquired into the matter, and in all probability entirely erroneous. There is no available evidence whatever of the existence of any such army regulations or practice concerning immediate self-disinfection as are in harmony with what is advocated by the Society for the Prevention of Venereal Disease. If such regulations do exist they must be concealed with remarkable success

and carried out very inefficiently. The rest of Dr. May's letter consists of a repetition of mere opinions, expressed by him in very fallacious logic, to the effect that the Society's instructions sanction and incite to "immorality." What amount of weight can be attributed to any of Dr. May's opinions on this subject will become apparent when it is remembered that he was for some time secretary to the National Council for Combating Venereal Diseases, which has always opposed scientific prevention by medical means; that later he began to speak fervently in favour of medical prevention, and joined the Society he now so grossly misrepresents; and lastly, that he subsequently changed his mind again, resigned his membership of that Society, and went back to the "National Council."

January, 8th.

H. B. D.

CLAUSE 7 OF THE CRIMINAL LAW AMENDMENT BILL.

SIR,—Since in Clause 7 of the Criminal Law Amendment Bill the suggestion has been made to penalize any person imparting venereal disease to another person, and to penalize solicitation on the part of a person suffering from venereal disease, I have been attempting to inquire into the history of cases coming for treatment to a clinic from this point of view. I have come to the conclusion that the difficulty in the way of obtaining evidence will make Clause 7 a possible source of profit to those wicked women who are ready to take any means to mulet men, but I fear that it will be of little or no use to the women who are sinned against, even if it does not lead to the men who have wronged them actually incriminating them as the source of the disease. The difficulties it will bring to medical men and women are obvious. These should be ignored if the clause were likely to work justly, but the possibility of our being used to give evidence by order of the court, which evidence may tell against what we believe to be the truth, is a prospect we must seek to avoid.

May I give a few examples to illustrate how such a clause might be used to obtain blackmail or cause a miscarriage of justice?

1. A wife, married three months to a seaman, appeared with generalized syphilis in a communicable form. If this woman brought an action against her husband, the evidence of the medical officer who examined the wife would be against the husband. Even if he could bring medical evidence to show he had no sign of syphilis, he would not have cleared himself, for he might have had a lesion and no sign be left. This woman admitted that she had been infected before marriage, and thought herself cured after a few injections. If she chose to say nothing of this, could she not use Clause 7 to levy blackmail on her husband?

2. A wife with generalized syphilis in a communicable form gave a history that signs had previously appeared in her husband. Again, might not the medical officer under Clause 7 be compelled to give evidence for the wife, though he or she might believe the wife guilty? This wife volunteered the information that she had exposed herself to infection from a man she had never seen before nor since, "because the money would be handy over the week end," that she had exposed her husband to infection the same evening, and that he had developed the disease first. If she had not volunteered this statement, would she not have had a good chance under Clause 7 of incriminating her husband?

3. A wife with generalized syphilis in a communicable form demanded a certificate to prove she was free from venereal disease because her husband threatened to divorce her unless she obtained such a certificate. In this case the medical officer could be obliged by the court to give evidence which would incriminate the wife; yet I believe that woman sinned against by the husband, who subsequently deserted her.

Before this clause becomes embodied in an Act of Parliament, can the British Medical Association do anything to so modify its wording that vexatious litigation and possible miscarriage of justice may be prevented? So far as the intoleration of the word "knowingly" goes, I am afraid it will not do more than deter wicked men and women from getting treated at clinics, whence evidence of their knowledge may be forthcoming. Will it prevent them from going to medical men privately, and using them as pawns to play their game?

If the clause cannot be so worded as to make it impossible for it to be used to work more harm than good, cannot the British Medical Association do something to get it omitted from the Act?—I am, etc.,

Cardiff, Jan. 2nd.

ERIE EVANS, M.B.

THE RISKS AFTER OPERATIONS FOR TONSILS AND ADENOIDS IN OUTDOOR CLINICS.

SIR,—That the operation for the removal of tonsils and adenoids is often far from satisfactory, sometimes fatal, not infrequently complicated with severe septic affections, and that it far too often fails to remove the symptoms for which it was done, even when repeated more than once, can hardly be put down merely to negligence of the hospital authorities in providing suitable accommodation, since it is well known that such unfortunate occurrences are to be noted even when every precaution is taken at the time and for the period of convalescence.

The troubles would appear to arise largely from the lack of preparation and of education of the patient beforehand. In other conditions where operation is found to be necessary surgical cleanliness is universally aimed at. Surely this scientific principle should be applied to the throat and nose.

In many cases when the patient is already on the table, the nasal cavities themselves as well as the nasopharynx are found to be packed with mucopurulent discharges, and in advanced cases of nasal stasis one is apt to find that the child has never learnt the elementary hygienic practice of clearing its upper air passages by blowing the nose fully and correctly. In such cases the teaching of this, the only method of dealing safely with one of the most destructive of the waste products, is a work of skill and of patience.

The teeth, too, are often in a neglected state, and the fact that the mouth and the nose are both parts of the same cavity is overlooked. Mouth-breathing, too, has been the habit for so long that soft foods have taken a chief place in the diet. The teeth then have become loose and the gums septic.

Before one can reasonably hope to be more or less safe and avoid the complications to which Sir William Milligan calls attention in his letter of December 20th, 1920, these details should have the attention necessary, as they do elsewhere.

The nose appears to be an efficient filter of most of the air borne germs—if not of all—but it can only do its work if it is kept in a healthy condition, free from all contaminating collections. Good habits must be instilled into the child in its early days. Were the domestic animals to store their waste products of respiration till these reached an advanced state of putrefaction, by drawing them back into their heads as children are so often allowed to do when they sniff, they would become unbearable and a great source of danger to themselves, their kind, and their owners.—I am, etc.,

OCTAVIA LEWIN,

Rhinologist to the R'ol of Honour Hospital, Paddington, and to the London County Council.

London, W., Dec. 28th, 1920.

SIR,—All those who have anything to do with these cases must welcome the discussion now taking place. I have always looked upon the way in which they were treated in hospital after operation as almost a scandal; there is no need to emphasize the risks involved, but I do think it is important that the profession should speak plainly.

More than twenty years ago I remember asking a friend who had operated on a patient of mine in a nursing home why, when he kept the child in for five days after operation, he sent his hospital patients home in as many minutes; his reply was almost in the words that I see used by one of your correspondents: "It is a highly unsatisfactory, but, under existing circumstances, necessary procedure." "To expect hospital authorities to provide the accommodation for the ideal treatment of these very numerous cases is, I think, unreasonable."

It is because we have been saying this to ourselves for twenty years that so little has been done to improve matters; the public will do nothing so long as we allow things to remain as they are, and this applies not only to the particular case now being discussed, but to the whole question of hospital accommodation. We are responsible for the education of the public as to the need of making provision for those large classes of cases which require, but at present do not receive, institutional treatment—such, for instance, as the numerous medical cases which have not in the past been generally considered as hospital cases, maternity cases and others that it is not necessary here to

detail. Although the present moment is inopportune for the actual provision of these beds, there is no need for us to delay our campaign of education; we must make it generally realized that these things are essential for the public welfare, and we should now be making our plans ready to put them into operation as soon as opportunity occurs.—I am, etc.,

Bradford-on-Avon, Jan. 3rd.

CHAS. E. S. FLEMMING.

EPILEPSY CONSIDERED AS A SYMPTOM.

SIR,—In his article on this subject in your issue of January 1st, Dr. Taylor, correctly, as I think, insists that epileptic convulsions may occur as a syndrome in various morbid conditions and that there is no disease entity to which the term epilepsy can be applied. He rightly urges that "each case of recurring convulsion must be studied by itself," yet he states that he has been "not a little disappointed and surprised at the tendency which has lately become obvious towards an attempt to approach its explanation on other grounds than that of physical disturbance." If epileptiform seizures may occur as a symptom in a variety of morbid states, as Dr. Taylor is at pains to show is the case, why should he be either disappointed or surprised when investigators of the symptom approach the subject open-mindedly and are prepared to take into consideration, not only physical, but psychical, disturbances as of etiological significance? The very fact that "there is no such thing as a case of ordinary epilepsy" should deter anyone from undertaking observations on this symptom with a preconceived limiting hypothesis in mind. Many eminent authorities have investigated the subject of epilepsy from various points of view, and have profitably extended their studies to include also the interparoxysmal period. Indeed, it is chiefly to those who have refused to confine their attention wholly to physical disturbances that we owe the conception of epilepsy as a syndrome, not as a disease. I am not presumptuous enough to take up the defence of those who have disappointed and surprised Dr. Taylor, but I should like briefly to give the histories of two cases which came under my care last year, in order to show that psychic factors may in some instances be responsible for the symptom of epilepsy. Dr. Taylor wisely says that a study of Jacksonian attacks is likely to be illuminating, and my first case is of this nature.

He was a young man, aged 22, of good family and personal history. He had served as a naval gunner on a merchant ship during the war. On the first night after his demobilization he had an epileptiform seizure, and continued to have them almost every night until he came under treatment in June, 1920. In the daytime he had typical Jacksonian fits beginning with movements in the fingers which spread up the right arm. The arm was gradually brought up in an extended pose to the level of the shoulder, with the index finger pointing, but the hand otherwise tightly closed. These attacks could be aborted if the arm were tightly seized and rubbed; but if this were not done unconsciousness and generalized convulsions often ensued. The Jacksonian fits invariably occurred in the afternoon, between 3 and 5 o'clock, and at the time he came to me he was having three or four every afternoon.

After taking a careful history I put the patient under light hypnosis, when he revealed the following repressed experience. One afternoon, while he was acting as gunner on a ship in a convoy off the north coast of Ireland, a hostile submarine had emerged at a range of only 500 yards. He pointed her out excitedly to his mates, giving the range. They opened fire, but were over their mark, and the U boat submerged but only to reappear at a greater range. Again they fired, but unsuccessfully, and again the U boat submerged. It was not seen again, but the watch was doubled, and the patient ordered to his bunk immediately, as he would have to take two consecutive watches of four hours each (actually from 12 midnight to 8 a.m.). His state of nervous tension and apprehension under these conditions may well be imagined. This memory, recalled under hypnosis, was then restored to his general consciousness, and he has never since that day had a Jacksonian fit.

He is also free from epileptiform seizures at night, though for a time, after any unusual excitement in the day, he used to toss about in his sleep, call out "We will give it them," and occasionally fell out of bed. As space is

limited I will make no further comment on this case, which seems to me to tell its own tale. No drugs or any other form of treatment were employed.

Dr. Taylor mentions the so-called "nocturnal epilepsy," and suggests that the condition of sleep rather than the time of day determines the onset of the convulsions. The following case supports this conclusion, though it does not favour his further presumption that some condition of nutrition or circulation is the cause of the convulsions.

A young man, aged 23, enlisted at the end of 1914, and was sent to work on munitions until March, 1917, when he was called up for training. In August, 1917, he was being transported to France (Le Havre); the voyage was rough and prolonged on account of reported menace from submarines. The man felt very sick and exhausted. In this state he lay down and tried to go to sleep. He then began to twitch all over and went off into an epileptiform convulsion. On arrival at Le Havre he was so helpless that he had to be carried off the boat to hospital. He was discharged from hospital in a week, and after a short stay at a convalescent camp was sent up to join his battery at the front. After a few days the battery was subjected to a heavy bombardment. The man was at the commencement of this in a dug-out by himself, but he rushed out and entered another dug-out which contained two other men. There he had another epileptic seizure. He was evacuated to the base and then to the United Kingdom. At Brighton he had frequent seizures which lasted about twenty minutes and always occurred at night, except on one occasion when he went to sleep in the afternoon and then had a convulsion. Eventually he was seen in a "fit" by the medical officer, certified as epilepsy and discharged from the service.

At the time he was sent to me he was having seizures about once a fortnight. They always occurred at night, generally when he was in a twilight or half-asleep state. Often before the convulsion came on he would partially wake up and lie for some time in a dreamy condition; then an aura as of the smell of a boat would precede the onset of a convulsion. Next day he felt dizzy, dull, and lethargic. Psychological analysis was undertaken, and the patient came to realize the meaning of his attacks and the repressed fear which underlay their initiation. Since this he has only had two convulsions, both following certain excitations which were analysed and showed a direct stimulation of the original complex. In my opinion these two cases serve conclusively to show that amongst the many causes of the epileptic syndrome psychical ones have a place.

It is far from my intention to argue that psychical factors only produce the syndrome, but I equally deprecate any attempt to attribute it exclusively to physical disturbances, whether these be an undefined cortical irritation, nutritional or circulatory changes, or endocrine dysfunction. In agreeing to consider epilepsy as a syndrome and not as a disease let us also agree to be entirely unbiassed in our search after its many possible etiological determinants.—I am, etc.,

Birmingham, Jan. 8th.

ALFRED CARVER.

ANGIO-NEUROTIC OEDEMA.

SIR,—I was much interested in Dr. Swan's letter upon this subject in the JOURNAL of January 8th. I fear, however, that he may be disappointed as to the curative value of horse serum. Some years ago I had a conversation with Sir William Gowers, who remarked that there were probably palliatives, but probably no cure, as he considered this condition to be an expression of the "gouty diathesis." I have been fortunate in seeing my share of these cases, and, while not quite in accord with Sir William as to the origin he thought invariable, I must confess I have never yet seen a case in which recurrence, sometimes long delayed, has not taken place. I gave some of my experiences of this disorder in a memorandum to the LANCET, June 2nd, 1905, and to your JOURNAL, May 22nd, 1915, and will now but repeat that it appears to me to have its place amongst the paroxysmal neuroses. Whether or not it is (oppositely) related to epilepsy is an interesting theory. Perhaps Dr. Davis, who recorded a case in the JOURNAL of April 3rd, 1915, may have further remarks to make.—I am, etc.,

CLAUDE A. P. TRUMAN.

Exeter, Jan. 9th.

THE BEGINNINGS OF LIFE

Sir,—Your interesting article suggests that biology is played out and that chemistry can tell us all about it. It appears that the chemists have proved that "fresh water and marine algae" get their N from the air. There is nothing new about this (Green, *Vegetable Physiology*, 1900, p. 179). Most of the N fixing algae turned out to have the N fixed by symbiotic bacteria. Still in regard to some the evidence was suggestive. Probably Professor Moore and his associates have definitely settled the matter for certain species, but this would scarcely justify generalization. Your last sentence, however (probably quoted from the chemists), proclaims the general misapprehension of the terms bacteria, fungi, and algae.

In amoeba there is a nucleus, cytoplasm, contractile vesicle, etc. It is a lowly organism compared with "marine and fresh water algae," but it is by no means primitive. Bacteria are much nearer to primitive plants because no nucleus is demonstrable in the largest, and simple cellular division is the only mode of increase. Some have acquired a cell wall which enables them to form spores, but absence of nucleus imposes a limit of one spore to one bacillus. In the absence of photosynthesis nutrition may be difficult, but there still survive nitrifying bacteria which form combined C without chlorophyll (Bower, *Botany of the Living Plant*, p. 165). Even these have solved the N and C riddle, yet Moore and Webster think it more promising to study such "marine and fresh water algae" as could exist in the "primordial world."

Out of their legions of algae let us take the most primitive, the unicellular blue green. In a few the mode of increase is almost as primitive as in the bacteria, yet the lowest has a cell wall and colouring matters which include chlorophyll. For a tiny protoplast the synthesis of chlorophyll was a mighty achievement, and marked the beginning of a new epoch. But the spark of life flickered fitfully for ages before this, and it is possible that bacteria are the sole survivors of the pre chlorophyllous age.

In order to compare them with bacteria the blue green algae are often called Schizophytes, which is pernicious nonsense. It is certain that 70 per cent of known forms increase by homologous and spores and not by fission, and that some branch habitually. Besides, there is always a demonstrable incipient nucleus the existence of which is rendered possible by food reserves accumulated by the chlorophyll. Cellular division is always amitotic. Nevertheless, the nucleus remains an open and imperfect one, and this accounts for complete absence of sexuality (West, *Algae*, 1916, p. 39).

In the case of Dodder we may speak of degradation, because in its flowers and in its tissues we have evidence of its origin and of its fall. But what evidence is there that bacteria are degraded algae? Every other division of plants has contributed to the saprophytes—why not the lowest, the bacteria? Contrary to what obtains in the bacteria, in the fungi there is evidence that they are derived from algae.

It has been pointed out that the achievements of the blue green algae were the synthesis of chlorophyll and the differentiation of part of the cytoplasm as a nucleus, and that they were only partially successful with the nucleus and failed to reach sexuality. Consequently their line of development leads into a blind alley, and they helped evolution mainly by contributing organic material for the needs of others. One must go back to the common stock (now enriched with this material) to find a starting point for higher forms. From a crowd of simple forms botanists are agreed that a type emerged which is fairly represented by *Ulothrix*. Unicellular, sometimes with and sometimes without chlorophyll, but always possessing a stable nucleus, it is mistle for part of its life, but encysted in times of stress. And the latter stage became more or less fixed—a plant—in such forms as *Protococcus*, *Chlamydomonas*. The nucleus was soon perfected, mitosis established, and sex developed with an increasing complexity of structure in the plants which issued in the green, the brown, and the red algae to colonize successfully the waters of the world.

For our purpose it is sufficient to direct attention to one branch of the green algae which terminated in *Vaucheria*. Mr. Moore remarked (*Journal of the Royal Microscopical Society*, 1910 p. 183)

"The Phaeomycetes are most nearly in touch with the algae, there is the same structure save in the absence of chlorophyll,

this last feature in reality constitutes the only difference between many and such algae as *Vaucheria*." And he added (p. 185) "the Oomycetes, the most primitive fungi, would come from *Vaucheria*," and he explains (p. 21) that in these lowly fungi "reduction in number of the chromosomes, from eight to four, takes place in the gametogenesis."

It will now be understood how far astray are those who link up bacteria with organisms so elaborate as even the lowest fungi. The only possible view is that the fungi are certain higher algae which have become saprophytic and achlorophyllous. Now we can understand that Moore and Webster prefer to work, not with the complex and atypical, but with the simple algae.

Such a dissertation is provoked by the fact that in recent years medical writers have been spinning yarns about the fungi. Just before the war the magazines told us how bacteria and yeasts arise *de novo* in test tubes. The nucleus of a torula is more complex than that of the blue green algae, and bacteria have no nucleus at all, yet we were assured that the first as well as the last arise indiscriminately as the result of a cross between a sunbeam and a salt solution. In a popular book Professor B. Moore has almost acquiesced in this, in spite of the absence of marine and fresh water algae. In your own columns recently a writer described a method of culture by which a meningococcus was transformed into a meningococcus of which he gave photographs. The gulf that separates the meningococcus from the ascomycetes cannot be bridged by horticulture—I am, etc.,

ROBERT CRUK, M.D. Glasg.

West Ealing W., Dec. 29th, 1920

ARTIFICIAL LEGS.

Sir,—I have been much interested in reading the article on artificial limbs in your issue of December 18th, 1920. The very equitable way in which you have reviewed the situation leads me to believe that some of my own experience may be of help in the very vexed question of light limbs.

In an experience of many years, not only in my own practice, but in that of my fellow artificial limb makers, the question of lightness has ever been present, and I venture to say that at the present time limbs for above knee amputation made of wood can be produced as light as their prototypes in duralumin.

No lighter limb exists than the British Anglesey type, which is practically constructed in wood (willow), only a small portion of the knee and ankle bolt being of metal. Numbers of these have been many years in wear, and the various British artificial limb makers can testify to the ease with which then patients have used, and are still using and wearing these limbs.

In your article you state that "the only type of limb which approaches in weight to 9 lb is that made for articulation at the hip." It is quite true that the type of limb for this amputation is one where the reduction of weight is of the greatest importance. Recently I have turned my attention to the construction of these limbs with duralumin lower portions, that is to say, the limb from the tilting table downwards is constructed in duralumin alone. It is a fact that where two limbs are made of equal weight—namely, one of leather tilting table and willow lower portion, the other with leather tilting table and duralumin lower portion—the duralumin limb will invariably be pronounced by the patient to be the lighter of the two, from the fact that the centre of gravity has been brought nearer to the body, and the dead weight of the lower limb has been enormously decreased.

By the above remark it would be inferred that both limbs, either made of willow or duralumin, weigh the same. In my earliest experience I found this to be the result owing to the amount of strengthening by steel required in the duralumin lower portion, but experiments have been made and the experience gained enables me to produce an artificial limb for through hip amputation with duralumin lower portion weighing seven pounds. This reduction in weight is a very considerable item.

Further, in your article you say that for amputation below the knee "no light metal limb has yet been put forward which has any advantage in weight or otherwise over wood, leather, and steel." For some considerable time past I have designed and made a light duralumin limb for below knee amputation which has been an

unqualified success in every way. A number of these limbs are now in use both for officers and for many of my private cases who had already been fitted with leather and wooden limbs, and each patient has expressed the greatest relief from weight and a more ready use of the limb when the duralumin limb is applied. These limbs are in use by many who are able to dance perfectly, ride, shoot over the roughest ground, play tennis, golf, and follow the life they led previous to their disability; amongst lady patients, several of whom are delicate, the change from the old limb to the duralumin limb has been of the greatest benefit.

In the concluding paragraph of your article you state that "the Ministry of Pensions may have experienced insuperable difficulty in an attempt to persuade the Treasury to approve the expenditure of nearly £100 for each of a large number of limbs." This sum is quite fantastic, and approximately half this amount is now sufficient to provide a perfectly constructed duralumin limb for practically any amputation.—I am, etc.,

F. G. ERNST.

Branch of Associated Surgical Appliance Makers, Ltd.,
Charlotte Street, London, W., Jan. 5th.

FAT-SOLUBLE "A" CONTENT OF OILS.

SIR,—I regret to find on reading through Professor Halliburton's reply to my letter published in your issue of December 11th, 1920, that the purpose of that communication is liable to be misunderstood. As a result of my own difficulties in consulting the literature dealing with this subject, I wished to call attention to the necessity for greater precision in the description of samples of oils and fats used for experimental feeding. Edible oils and fats of commercial quality are prepared by a variety of processes differing greatly in their possible effect on the original vitamin content; and the statement, for example, that coconut oil is deficient in fat-soluble "A," is of very little value either to the physiological worker or to the manufacturer. The objection raised by Professor Halliburton as to the difficulty of tracing the history of samples available for investigation is one which, I feel sure, is not insurmountable.

I would also take this opportunity of pointing out that I did not say that the Medical Research Council's report was worthless, but that certain results contained in it, examples of which I quoted, were, for the reason I have given above, practically worthless.—I am, etc.,

Port Sunlight, Cheshire, Jan. 4th.

A. D. STAMMERS.

Medico-Legal.

THE DEFINITION OF INSANITY.

IN a case recently heard at the Central Criminal Court Sir Robert Armstrong-Jones, who had been called on the part of a prisoner charged with murder, expressed the opinion that the accused was insane when the crime was committed. Having answered certain questions with regard to suicide, the witness also stated that he did not agree with the rule laid down in Macnaghten's case. Referring to this in the course of his summing up, Mr. Justice Darling said: "That rule is binding on us. We take the law of England from the King's Bench and not from Harley Street; from the House of Lords and not from Wimpole Street or any other street." It is curious to notice that this is the only passage in the summing up which one leading daily newspaper thought it necessary to report.

In the event the jury found the prisoner guilty but insane, and he was ordered to be detained until His Majesty's pleasure be known. The learned judge's observation was hardly courteous to the witness, and, if intended to be jocular, it was ill-timed, seeing that the prisoner was on trial for his life; but there is no doubt that it is the legal, not the medical, view of insanity which will prevail in courts of justice.

In 1843 His Majesty's judges were summoned to advise the House of Lords in the case of one Macnaghten, who was charged with murder. Insanity had been pleaded as a defence. The opinion which the judges expressed has been adopted ever since. The material words are:

"The jury ought to be told in all cases that every man is presumed to be sane, and to possess a sufficient degree of reason to be responsible for his crimes, until the contrary be proved to their satisfaction; and that to establish a defence on the ground

of insanity, it must be clearly proved that at the time of committing the act the accused was labouring under such a defect of reason, from disease of the mind, as not to know the nature and quality of the act he was doing, or, if he did know it, that he did not know what he was doing was wrong."

Sir Robert Armstrong-Jones is not the first member of the medical profession to dissent from this opinion. In the latest edition of Taylor's *Medical Jurisprudence* the late Dr. F. J. Smith pointed out that in 1894 a committee of members was instructed by the Medico-Psychological Association to report on the subject. They did so in 1896. They concluded their report by saying that:

"While not approving the doctrines and definitions contained in the judge's answers to the House of Lords in 1843, we are at present unable to make any recommendations for the amendment of the law."

One of the points in dispute between the lawyers and the medical profession is the meaning which should be attached to the word "wrong" which occurs in the definition. The lawyer has his own conception of the word; and as it is his task to explain matters to the jury the result of a trial where insanity is pleaded is often curious. Nor are the lawyers themselves altogether satisfied with the definition.

In his presidential address to the Medico-Legal Society (printed in the JOURNAL of November 13th, 1920) Lord Justice Atkin referred to the matter. He expressed the opinion that there ought to be some change in the formula laid down in Macnaghten's case, but he went on to point out that,

"after all, order has to be maintained, and it is no use criticizing the formula in Macnaghten's case unless you can substitute some effective formula in its place which will not have the effect of removing all criminals from a gaol to an asylum."

Not only does the rule in Macnaghten's case hold the field, but, as was pointed out in a leading article published in this JOURNAL in 1914¹ when commenting on the case of Rex v. Felstead, a man who is found "guilty but insane" has no right of appeal from that part of the verdict which finds him insane, although it had been decided in a previous case (Rex v. McHardy) that he may appeal from that part of the verdict which finds him guilty! It follows that under the present law a man may be detained at Broadmoor for the rest of his natural life if the jury, under the direction of the judge, find that he was not responsible for his actions. Everything depends upon the view of Macnaghten's case which a particular judge lays before the jury. One learned judge is said to have boiled the matter down to a single sentence: "Could he help it?" Such a definition is much too vague—especially in a court of criminal jurisdiction.

As Lord Justice Duke intimated in the course of a speech which he delivered at the recent dinner of the Medico-Legal Society: "There should be no doubt upon a rule affecting matters of life and death." It ought not to be difficult for lawyers and doctors to put their heads together in order to arrive at a definition satisfactory to both; but in the meantime it is well to remember that in the vast majority of cases where insanity is pleaded in courts of law, medical testimony is decisive, and that is commonly the evidence of a single witness. For example, there are scores of cases in which the prisoner, on his arraignment, either refuses to plead or answers in such a way as to render it doubtful whether he understands the meaning of the question, "Are you guilty or not guilty?" The jury are then sworn to try whether he is or is not fit to plead, whereupon the prison doctor is called to speak as to his mental condition, and his evidence is absolutely conclusive.

It may be remembered that in 1914 there was appointed a Crime and Punishment Subcommittee of the Medico-Political Committee of the British Medical Association, which co-opted representatives of the Medico-Legal Society, the Medico-Psychological Association, the Bar Council, and the Law Society. This Committee considered at length the state of the law with regard to the legal responsibility for crime, with special reference to the opinions of the judges delivered at the request of the House of Lords after the trial of Macnaghten in 1843, and reported with recommendations to the Council of the Association, so that the suggestion of Lord Justice Duke has already been acted upon by the British Medical Association. In his *Digest of Criminal Law* (Article 27) Sir James Fitzjames Stephen suggested the following modifications of the opinions of the judges:

No act is a crime if the person who does it is at the time when it is done prevented [either by defective mental power or] by any disease affecting his mind (a) from knowing the nature

and quality of his act, or (b) from knowing that the act is wrong [or (c) from controlling his own conduct unless the absence of the power of control has been produced by his own default].

But an act may be crime, although the mind of a person who does it is affected by disease, if such disease does not in fact produce upon his mind one or other of the effects above mentioned in reference to that act.

N.B. "Wrong may mean (1) morally wrong, (2) illegal."

Ultimately the Subcommittee expressed the opinion that the following might be accepted by the medical profession as a fair definition of responsibility for crime in preference to the ruling laid down by Sir James Fitzjames Stephen:

No act is a crime if the person who does it is at the time when it is done prevented either by defective mental power or by any disease affecting his mind:

(a) From knowing and appreciating the nature and quality of his act or the circumstances in which it is done; or

(b) From knowing and appreciating that the act is wrong; or

(c) From controlling his own conduct unless the absence of the power of control has been produced by his own default.

N.B. "Wrong" means morally wrong or illegal.

The Subcommittee, therefore, took the suggested modifications of Sir James Fitzjames Stephen as the foundation of its own report, and made a further modification as acceptable to medical opinion, after consultation with the legal members of the Committee. Sir James Fitzjames Stephen's last sentence might, perhaps, have been retained as more exact in its phrasing; the Subcommittee's form of words might imply that morally wrong and illegal were synonymous. The Subcommittee reported further that there was need for reform in other matters related to this question—for example, regarding the evidence before the Court as to the mental condition of accused persons; the position of persons found "guilty but insane" and the ruling laid down that such persons had no right of appeal; and the desirability that medical officers of prisons should have had experience in the diagnosis and treatment of insanity.

Obituary.

R. J. BLISS HOWARD, M.D., MCGILL, F.R.C.S. ENG.

WE regret to have to announce the death, on January 9th, after a long and painful illness, of Dr. Robert J. Bliss Howard. He was born in Montreal in 1859, the son of Dr. Robert Palmer Howard, Professor of Medicine in McGill University, one of the three teachers Sir William Osler recalled as having had most influence on his mind in his early years. When the younger Howard began his studies at McGill University Osler was professor of medicine, and throughout his life he remained Howard's firm friend. Howard graduated B.A. with first class honours in natural science in 1879, and M.D., C.M., taking the gold medal, in 1882. After completing his career at Montreal, Howard attended the London Hospital, and in 1882 became M.R.C.S. and L.R.C.P.; two years later he became F.R.C.S. He studied also in Berlin, Vienna, and Leipzig. For some years he was associated with his father in practice in Montreal, and was also demonstrator of anatomy and surgery at McGill University, and pathologist and assistant surgeon to the Montreal General Hospital. In 1888 he married the only daughter of Sir Donald Smith—afterwards Lord Strathcona and Mount Royal. For a time he practised in London as a laryngologist, but after some years retired and devoted himself to country pursuits, especially shooting and fishing. During the war he organized the Mount Royal Hospital for Officers at Bath; he worked also at the 3rd London General Hospital, in which he took a great interest. He is survived by Lady Strathcona. They had a family of three sons, all of whom served in the war, and two daughters. His eldest son served throughout the whole of the war in France. His second son was killed in action, and the third son was severely wounded. Each of his daughters married naval officers—Commander Kitson and Lord Congleton.

Dr. HERBERT SPENCER writes: The death of Dr. R. J. Bliss Howard will arouse feelings of profound sorrow in the hearts of those who knew him. He was a man of very considerable intellectual powers and had a distinguished academic career at McGill. His manner, sometimes flippant and bantering, occasionally misled those who did not know him to think him superficial; but those who knew him intimately, as I did for nearly thirty years, found him to be a sincere, true-hearted, unselfish, and loyal friend. He was keenly interested in shooting, fishing,

and natural history. The happy days spent sporting in his company at Glencoe and Debdon will be to many a very pleasant memory, and the patience with which he spent his last sad days an example of courage and resignation.

LAURENCE HERSCHELL HARRIS, M.B., CH.M.,

Sydney.

DR. LAURENCE HERSCHELL LEVI HARRIS has died at his residence in Sydney after an illness extending over three months. He was born in Sydney in 1871, and educated at the Sydney Grammar School and afterwards at the Sydney University, where he graduated M.B., Ch.M. in 1896. After graduation he became one of the resident medical officers at the Sydney Hospital, and subsequently was appointed medical superintendent. As he had always been keenly interested in photography he naturally took to x-ray work, a subject which at that time was being introduced all over the world. He was thus one of the pioneers in this branch of medical work, and was the recognized leader in it in Sydney. Like most workers with the x-rays he was attacked by dermatitis, and this led to the loss of one of his fingers as well as to constant trouble with his hands for many years. He was appointed honorary radiographer to the Sydney Hospital in 1900, a post he held for fifteen years; he was then appointed honorary consulting radiographer. He was subsequently appointed honorary radiographer to the Royal Prince Alfred Hospital, and at the time of his death he held this appointment, and a corresponding post at the Royal Alexandra Hospital for Children, at the Tubercular Dispensary, and at the Australian Jockey Club Home for Wounded Soldiers.

In 1914, while away on holiday, he was present at the British Medical Association meeting at Aberdeen, and on learning that war was imminent with Germany he volunteered his services as radiographer for any Australian unit which might be organized. He accepted the post of radiographer to the Australian Voluntary Hospital, and he organized his department so efficiently that on arrival at St. Nazaire on September 5th, 1914, seven hours after the equipment was landed at the hospital x-rays were available for the benefit of the wounded who were arriving from Mons. In the spring of 1915 he was ordered to join up with the No. 3 Australian General Hospital at Lemnos. The outfit which he had selected and taken out with him to Lemnos was subsequently pronounced by the late Sir Victor Horsley to be the best equipped x-ray outfit in the Mediterranean Expeditionary Force. Although hampered by ill health and under great disadvantages of climate and surroundings he continued to do excellent work until he was invalided to England, in consequence of the affection of his hands, just about the time of the evacuation of Gallipoli. He subsequently returned to Sydney and resumed his hospital and private work.

All through life his interest in nurses was manifested by many acts of kindness. All his military pay in the early months of the war was devoted to providing them with extra and much needed comforts. In his will he has left:

"To the treasurers of the Royal and Prince Alfred and Sydney Hospitals the sum of £4,000 to be held by them upon trust to apply the income in equal proportions, so far as may be considered necessary, in each year in rendering pecuniary assistance to nurses employed at these hospitals who, either during their course of training or while on the staff, shall be rendered temporarily incapable through illness or accident from continuing to discharge their duties, with a view to afford such nurses an opportunity for a change of air and scene, and thereby assist them in regaining health."

Harris was a man of most kindly disposition, ever willing to share his knowledge and experience with others, and was much liked and trusted by his fellow medical men, who were always ready to take his advice as to the treatment of any of their relatives. He was given a military funeral, which was attended by a large number of his fellow military officers and other medical men. The service at the graveside, in Rookwood Cemetery, in the Jewish section, was conducted by Rabbi Cohen.

Dr. ALFRED WILSON ENNIS, who died recently at Thurcaston, was born at Kingston-on-Thames Grammar School 1850. He was educated at the Westminster School, and Guy's Hospital, took the diplomas of M.R.C.S. and L.S.A. in 1872, and graduated M.D. Durh. in 1898. He

Universities and Colleges.

UNIVERSITY OF OXFORD.

THE next examination for the Diploma in Ophthalmology will be held on July 18th. Full particulars of courses of instruction, which commence on April 25th, can be obtained on application to Mr. P. H. Adams, Margaret Ogilvie Reader in Ophthalmology, 53, Broad Street, Oxford.

UNIVERSITY OF LONDON.

A MEETING of the Senate was held on December 15th, 1920. The following were recognized as teachers of the University in the subjects and at the institutions indicated:—*King's College*: Dr. Orlando Inchley (Pharmacology). *St. Bartholomew's Hospital Medical School*: Mr. T. P. Dunhill (Surgery). *St. Mary's Hospital Medical School*: Dr. C. McMoran Wilson (Medicine). *National Dental Hospital and College*: Mr. J. L. Dudley Buxton (Dental Surgery), Mr. A. B. G. Underwood (Dental Anatomy).

Sir Cooper Perry was appointed a member of the King's College Delegacy for the remainder of the period March 1st, 1920, to February 28th, 1921, in succession to Sir Charles J. Lyall, deceased, and a member of the Central Council of the Federated Superannuation System.

The annual report of the Graham Legacy Medical Research Committee, giving particulars of the general progress of the laboratory, was received, and Professor A. E. Boycott, F.R.S., was reappointed director of the laboratory for one year from January 1st, 1921.

It was decided to institute a university chair of anatomy at St. Bartholomew's Hospital Medical School.

It was resolved that a candidate for the Diploma in Psychological Medicine who has passed the examination of M.D. in Branch III, Mental Diseases and Psychology, be exempted from examination in psychology and psychological medicine, and be awarded the Diploma in Psychological Medicine on satisfying the examiner for the diploma in Part A (i), "Anatomy, histology, and physiology of the nervous system," and Part B (i), "Neurology."

Dr. F. R. Fraser, as already announced in the JOURNAL, has been appointed to the university chair of medicine, tenable at St. Bartholomew's Hospital for a period of four years from October 20th, 1920.

The William Julius Mickle Fellowship of the value of £200 has been awarded to Miss Harriette Chick in recognition of her important work on diseases due to defective nutrition.

The University medal at the M.B., B.S. examination (October, 1920) has been awarded to Mr. Ronald M. Handfield-Jones of St. Mary's Hospital.

SOCIETY OF APOTHECARIES OF LONDON.

THE following candidates have been approved at the examinations indicated:

STURGERY.—*H. Davies, *R. F. Divecka, *W. Kilroe, *†M. Meiglave, †J. B. Williamson.

MEDICINE.—*H. Davies, *H. Dinerstein, *C. T. Gasking, *H. D. L. Jones, *†R. J. Little, *†E. R. D. Nagel, *†W. R. Ranson, *C. Verheyden.

FORENSIC MEDICINE.—S. Davies, R. J. Little, S. E. J. Miedema, W. R. Ranson, B. W. Roffey, C. Verheyden, J. B. Williamson.

MIDWIFERY.—J. H. Cooper, S. Davies, S. E. J. Miedema, M. Tcherny.

* Section I. † Section II.

The diploma of the Society has been granted to Messrs. S. Davies, R. F. Divecka, R. J. Little, E. R. D. Nagel, and W. R. Ranson.

The Services.

HYGIENE IN THE ARMY.

A RECENT Army Order provides for the establishment of command schools of hygiene at Aldershot (when the transfer of the school at Blackpool is effected); Hertford Barracks, Hertford; Strensall Camp, near York; Dregghorn Camp, near Edinburgh; Hulsea Barracks, Portsmouth; and Carrickfergus. These schools are to be permanent centres of instruction for staff and regimental officers and for regimental sanitary personnel; and they will maintain close liaison with neighbouring units in order to facilitate the demonstration of the principles of practical hygiene on model lines. Four classes for officers will be held annually, and the classes for regimental non-commissioned officers and men will extend over a period of three weeks. Classes for personnel of the Royal Air Force will run concurrently with the army classes, and Territorial Force sanitary companies will be attached to the command schools for instruction during their period of training.

DR. A. J. H. MONTAGUE, Commandant of the Workshop Nursing Division (V.A.D.) since its inception, and Mrs. Montague as lady superintendent, have, on the occasion of Dr. Montague's retirement from active practice, been presented by the members thereof with a Doulton-ware dinner service as a mark of their esteem.

had practised at Belgrave, Leicester, for over forty years, and only removed to Thurstaston in September last. At the end of 1919 he resigned his professional appointments, but still continued his private practice. He took great interest in local affairs, was a J.P. for Leicestershire, chairman of the trustees of the Belgrave Church Estate Charity, and a member of the Leicester and Rutland Division of the British Medical Association. Dr. Emms is survived by his widow and a married daughter.

DR. ROBERT SLATER MAIR died in London on December 21st, 1920, aged 94. He was born at Paisley in 1826, was educated at the universities of Edinburgh and Glasgow, and took the M.D. at St. Andrews in 1850, and the F.R.C.S. Edin. in 1863. Soon after qualifying he went to India, and spent seventeen years in private practice at Madras, also holding the posts of deputy coroner of that city and medical officer of the local volunteer corps, the Madras Volunteer Guards. While in India he wrote two once popular works, *The European in India and Medical Guide to Anglo-Indians, 1873*, and *On the Management of Children in India, 1875*. On his return to England he set up in practice in Bayswater, and for forty years held the post of inspector of factories for the City of London, till he resigned some four years ago. He had also been physician to the Persian Embassy, and was a vice-president of the Harveian Society. While in Madras he married Miss Mary Anne Batchelor in 1862, and in 1912 celebrated his golden wedding. He had a family of five sons and three daughters, all of whom, except the eldest son, survive him. Two of his sons, Lieut.-Colonel R. J. B. Mair, late R.E., and Colonel G. T. Mair, D.S.O., late R.A., received the C.M.G. for their services in the late war.

WE regret to record the death in tragic circumstances of Dr. ALEXANDER WILLIAM MATHER, of Norton-on-Tees. Dr. Mather studied medicine at the University of Edinburgh, graduating M.B., Ch.B. in 1912, and proceeding M.D. in 1916. After acting as resident house-physician at the Royal Infirmary, Edinburgh, resident surgical officer at St. Mary's Hospital, Manchester, and senior house-surgeon at the North Riding Infirmary, Middlesbrough, he settled in practice two years ago at Norton, where he was very popular. His death was the result of burns produced by an explosion in his garage while he was preparing his car for a professional visit. Dr. Mather leaves a widow and young child.

WALTER GIBSON MARSDEN, late Captain R.A.M.C.(T.C.), died in St. Thomas's Hospital on December 19th, 1920, after a long illness, contracted on active service. He was the eldest son of Walter Marsden, of Fairfield, Manchester, and was educated at St. Thomas's Hospital and at Cambridge, where he graduated as B.A. in the Natural Science Tripos in 1908 and as B.C. in 1911, also taking the M.R.C.S. and L.R.C.P. London in the latter year, after which he filled the posts successively of house-surgeon, casualty officer, resident anaesthetist, obstetric house-physician, and resident accoucheur at St. Thomas's. He took a temporary commission as lieutenant in the R.A.M.C. on April 26th, 1916, and was promoted to captain after a year's service. Before going abroad he served in the British Red Cross Hospital at Netley.

WE very much regret to record the death at the age of 54 of Mr. S. ARCHIBALD VASEY, F.I.C., F.C.S., who was for thirty years consulting analytical chemist to the *Lancet*. For a long succession of years he attended regularly the annual meetings of the British Medical Association, and his interest in the Annual Exhibition of Foods and Drugs made him a familiar figure to many members of the medical profession. Mr. Vasey was an able chemist, a fluent writer, and the most kindly and agreeable of companions; his genial personality endeared him to a wide circle of friends. He died at his home in Bromley, Kent, on January 7th.

Medical News.

THE committee of the Royal Medical Benevolent Fund Guild, anxious to devise new means of obtaining the financial support so greatly needed, recently gave a dance at the house of Sir St. Clair Thomson, who generously bore all the expenses, including a band and refreshments. The Guild benefited to the extent of over £100. Anyone inclined to follow this generous example should communicate with the Secretary of the Guild, 19, Portland Place, W. 1.

A SPECIAL course of systematic lectures and clinical demonstrations will be given at the National Hospital for Diseases of the Heart, Westmoreland Street, W. 1, on Mondays, at 5.30 p.m., commencing on January 17th.

THE course of lectures on the History of Science at University College, London, was resumed on January 12th, when Dr. Wolf gave an introductory lecture on the general history and development of science. On Tuesdays at 5.15 p.m., beginning on January 18th, Dr. Charles Singer will lecture on the history of the biological and medical sciences from early times to the eighteenth century, his course on the development of medicine in modern times will begin on Monday, March 7th, at the same hour.

A COURSE of twelve practical demonstrations on the management and feeding of infants and young children will be given by Dr. Eric Pritchard at the St. Marylebone General Dispensary, Welbeck Street, W., on Tuesdays and Thursdays at 10.30 a.m. and 3 p.m., respectively, commencing on January 18th. The fee for the course is £2 2s. Opportunities will be afforded to those attending the course of visiting, on Saturday afternoons, the Nursery Training School, 1, Wellguth Road, Golders Green, and seeing the methods employed in dealing with infants.

A NEW publication, *The American Journal of Hygiene*, is announced to appear this month. The editor is Dr. William H. Welch, and he will have the assistance of twenty three colleagues at Johns Hopkins University and elsewhere, and with Dr. Charles E. Simon as managing editor. The new journal is supported by the De Lamar Fund of the Johns Hopkins University, and it will be published by the Johns Hopkins Press, Baltimore. Its object is the publication of papers representing the results of original investigations in hygiene, using this term to cover all applications of the mathematical, physical, chemical, medical, and biological sciences to the problems of personal and public hygiene. It is proposed to issue at least six numbers a year, and the price, post free, will be 6.00 dols. a volume at home, 6.25 dols. for Canada, and 6.50 dols. in other countries.

NOTICES have been made regarding the continuance of the Maudsley courses for a diploma of psychological medicine. We are asked to state that, if sufficient applicants are forthcoming, Part I of the third course of lectures and demonstrations will be commenced in April. Intending applicants should communicate as soon as possible with the Director, Pathological Laboratory, Maudsley Hospital, Denmark Hill, S.E. 5.

ON Wednesday, January 19th, at 5.30 p.m., in the Psychological Laboratory, King's College, Strand, Dr. William Brown will begin a two terms' course of weekly lectures and demonstrations on experimental psychology for medical men who are preparing for the diploma in psychological medicine. The class is limited to ten members, and intending applicants should write at once to the Secretary, King's College, Strand, W.C.2, for particulars of fees, etc. Dr. Brown's opening lecture on psychopathology on Tuesday, January 18th, at 5.30 p.m., will be entitled "The structure of the normal personality."

A VENEREAL DISEASE COMMISSION was dispatched in September, under the aegis of the Colonial Office and the National Council for Combating Venereal Diseases, for the purpose of assisting local authorities in attacking the problem of venereal disease in the West Indies. In various local organizations are already carrying out propaganda work under the auspices of the National Council, and in Trinidad a branch is in process of formation.

VOLUME I of the fourth series of *Guy's Hospital Reports*, under the general editorship of Dr. A. L. Hurst, will shortly be published by the Oxford Medical Publications.

THE second Congress of the History of Medicine will be held at Paris in August, 1921.

THE twentieth annual report of the Canadian Association for the Prevention of Tuberculosis has just been published. It contains reports of the local antituberculosis societies

throughout the Dominion, which appear to be carrying on a great deal of valuable work with commendable keenness. The report includes also the transactions of the annual meeting of the association which was held at Vancouver in June, 1920, when papers were read by the president, the Hon. F. D. Schaffner, M.D., and others, and interesting discussions took place. In Vancouver itself the initiative was taken and the necessary funds raised for the well-equipped new tuberculosis dispensary now in existence there by a local business men's social club of only 150 members, the Rotary Club, which handled the dispensary, when completed, over to the city.

ON January 5th Dr. Smart Evans of Cardiff was charged before the stipendiary magistrate for making a false return in a vaccination certificate. According to the legal representative of the board of guardians, Dr. Evans, after vaccinating a child, had immediately certified that the operation was successful. The defendant was committed to the Glamorgan assizes personal bail being accepted in a sum of £50.

Letters, Notes, and Answers.

As, owing to printing difficulties, the JOURNAL must be sent to press earlier than hitherto, it is essential that communications intended for the current issue should be received by the first post on Tuesday, and lengthy documents on Monday.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the BRITISH MEDICAL JOURNAL also unless the contrary be stated.

CORRESPONDENTS who wish notice to be taken of their communications should authenticate them with their names—of course not necessarily for publication.

AUTHORS desiring reprints of the articles published in the BRITISH MEDICAL JOURNAL are requested to communicate with the Office, 429, Strand, W.C.2 on receipt of proof.

In order to avoid delay it is particularly requested that ALL letters on the editor's business of the JOURNAL be addressed to the Editor at the Office of the JOURNAL.

THE postal address of the BRITISH MEDICAL ASSOCIATION and BRITISH MEDICAL JOURNAL is 429, Strand, London, W.C.2. The telegraphic addresses are:

1 EDITOR of the BRITISH MEDICAL JOURNAL, Astology, Westland, 2 FINE, MANAGER, telephone, 2630 Gerrard.

3 MEDICAL SECRETARY, Mediverra, Westland, London; telephone 2630 Gerrard. The address of the Irish Office of the South Frederick Street, Dublin, telephone 4737, Dublin, and of quare Edinburgh (telegrams 4351, Central).

QUERIES AND ANSWERS.

"R. W. P." writes: Is there any special arrangement amongst the medical practitioners in Letchworth, Herts, with regard to the conduct of private practice in that town?

"A." No information as to any such special arrangements has reached us.

DISEASES OF THE NAILS

"H. R. H." asks for advice as to a textbook on diseases of the nails. Most of the textbooks on diseases of the nails give only brief outlines to treatment for splitting of the nail in woman there is no the lunula to the extremity suddenly becomes painful to the touch, then a red streak appears, which in a day or two forms a distinct fissure. This occurs from time to time in different nails.

"A." A good account of diseases of the nails may be found in Allbutt's and Rolleston's *System of Medicine*, vol. ix. To suggest remedies for the condition complained of is difficult, as in many cases the affection of the nails is only symptomatic. Probably some benefit would be obtained from the use of an ointment of oil of cade 1 in 20 in calicheic acid ointment 5. At the same time, mild application of x-rays should be given, about one half pastille or less every two weeks for four exposures.

LETTERS, NOTES, ETC.

NAME FOR ACCESSORY FOOD FACTORS

DR. JOHN BROWN (Blackpool) writes: The name 'vitamines' is given for the accessory food factors. We know now that the word is absolutely misleading. We need another or alternative name. The following have been suggested: Biofactors, biofactors, and vitagen; vitamins, vitamins, vitamins, biofactors, etc. I have submitted the names to several medical men. The following have been suggested: Biofactors, biofactors, vitamins. At the Cambridge meeting of the British Medical Association when vitamins were discussed,

I used the word "vitoids." Personally, I believe *biogens* is preferable. It agrees with many words derived from bios, such as biology, bioplasm, biological, biogenetics, biography, etc. It is not too late to adopt a new word.

DELIVERY OF CHILD AND PLACENTA IN UNRUPTURED MEMBRANES AT TERM.

Dr. JOHN WISHART (Newcastle-upon-Tyne) writes: Following the memorandum by Dr. J. H. Gilbertson in the *BRITISH MEDICAL JOURNAL* of October 23rd, I may say that out of 4,000 midwifery cases during the past twenty years I have had only two such cases as detailed by him. Is it possible that Nature, at one time, delivered all cases in unruptured membrane, and that the present procedure of rupturing membranes at the end of the first stage is wrong?

A NEEDLE IN A SEMILUNAR CARTILAGE.

Dr. JOHN R. HOWITT (St. Joseph's Hospital, Hamilton, Ontario, Canada) writes: The following case seems worthy of record. A man, aged 31, wa-admitted to hospital for operation for a dislocated left external semilunar cartilage. The patient had been sitting on a piano stool about a month ago when, on turning round, he slightly twisted his knee. A sharp pain came on which lasted nearly a week, and he could scarcely walk. At the same time he noticed a lump which appeared whenever he flexed his knee. Both the pain and the lump recurred again at intervals several times afterwards. He was operated upon by Dr. Olmsted, and the cartilage was removed. Buried in the cartilage itself and also projecting in part into the lower surface of the joint was a blackened piece of needle about 1½ inches long. The patient, on being questioned after the operation, stated that he had a hazy recollection of having swallowed a needle when a child. He was positive no needle had ever penetrated him otherwise; the only conclusion, therefore, is that the needle recovered in the excised cartilage at operation was the one he had swallowed about twenty-five years before.

TUBERCULOSIS.

Dr. J. S. PEARSE (Plymouth) writes: In your leading article on this subject on p. 907 you state: "Virgin subjects" (rural dwellers transferred to towns and certain native races) succumb to severe and rapidly fatal forms when first exposed to massive doses at close quarters." Do rural dwellers drink tuberculous milk? Are they more immune to tuberculosis than town dwellers? Why should they not become infected by bovine tuberculosis as the town dwellers are supposed to be?

Here is the history of the family of A. B., the members of which reside in a village in Cornwall. His father and uncles died of tuberculosis. A. B. and his brothers died from tuberculosis, all residing in the same village and neighbourhood. His sisters are all living, over 60 years of age. One is a very stout and big woman, another thin, active, and wiry, subject to rheumatism. A. B. had six sons and four daughters. One son in his twenties came to Plymouth in business, married, and shortly after died from tuberculosis. The youngest son, tall, and apparently healthy and clever, won a school scholarship and went to college. Shortly after he also died of tuberculosis. The remaining four sons reside in the village. One is a very stout man; another very tall, thin, and wiry; the other two are delicate. The four daughters also live at home in the village—all over 30 years of age, are well built, strong, and healthy-looking.

This family of rural dwellers would probably not be described as "virgin subjects," but there are those who would say so, because the two sons who left home died from tuberculosis. But if the bacillary theory is to hold good, they should have been immune to the six sons show derangement and growth, indicating want of the endocrine glands. Would this presence of toxins of tuberculosis in or in their father affecting the sperm and germ cells? A curious fact is that the female members of the family appear to have escaped tuberculous infection, or clinical evidence of it.

According to the statement made by Sir Dyce Duckworth, a rheumatic diathesis is inimical to tuberculosis, and it is also stated that an individual who is bald is not likely to contract tuberculosis. It would not be out of place to say that the action of the endocrine glands has an all-powerful effect upon the development and incidence of tuberculosis.

MOTOR SCOOTERS.

IN the *BRITISH MEDICAL JOURNAL* of November 27th, 1920, under "Queries and Answers," we published a note on motor scooters in which we said that this type of vehicle probably has a future, but that at present it is not possible to speak with confidence. More recently we have had the opportunity of examining a machine called The Whippet, made by Messrs. W. G. C. Hayward and Co. of Beaufort Works, Twickenham. We are inclined to think that under certain conditions and in some practices this scooter may prove of considerable service. In large towns it is possible that the greater dignity in progression conferred by the car may appeal to practitioners. But in the suburbs and in rural areas, especially if the roads are tolerably good, the scooter may well prove useful, whether for habitual use or as access-

sory to the car, and this view is confirmed by a medical man who is now using one of these scooters. The engine, four-stroke, 1½ h.p., is fitted with an exhaust valve lift in order to make starting easy. The wheels are broader than usual, and fitted with 18-in. tyres. The frame is very strong and is stated to have carried the weight of three persons. The strength of the frame and the size of the wheels are the main points which suggest greater reliability and usefulness as compared with some of the lighter machines. The seat is well sprung and very comfortable. A speed from three to twenty-five miles per hour is obtainable, and the petrol consumption is stated to be at least 100 miles to the gallon. The mechanism is very simple, and the scooter is said to be able to climb any hill. Economy in initial cost, in upkeep, and in mileage to the gallon of petrol and oil are points in favour of making the vehicle popular, especially in view of the car taxation now coming into force. An objection to the machine is that in rainy weather the rider will need the same sort of protection from wet and mud as is needed by the rider of an ordinary motor bicycle. Further, the greasiness of wood pavements, especially where there are tram lines, will probably render great care necessary in riding. The latter objection, however, applies to all rubber-shod vehicles.

AN IMPROVED EMBEDDING MEDIUM.

Dr. C. LOVELL writes from the Pathological Laboratory, Bethlem Royal Hospital: We have recently been using a new embedding medium, which may be of use to some of your readers. One part, by weight, of beeswax, is added to five parts, by weight, of paraffin wax (m.p. 50° C.). The whole is melted together and filtered in the hot air sterilizer. The medium gives excellent results with nerve sections. The beeswax gives sufficient tenacity to prevent any crumbling. The mixture melts at 51° C. to 53° C., and cuts smoothly at any temperature.

CATALOGUES.

WE have received from X-Rays, Limited (11, Torrington Place, London, W.C.1), a list of electro-medical appliances with prices, including the most recent models on the British market. Although a sectional catalogue, from which x-ray apparatus is excluded, it is most comprehensive, and in its hundred pages will be found described apparatus and accessories for use in electrical methods of testing and treatment, as well as such things as surgical lamps and electric sterilizers.

WE have received from the Edison Swan Electric Company (Limited), of Ponders End, Middlesex, a copy of a new list of "Ediswan" apparatus for obtaining the currents required by the radiologist. The principal feature of the catalogue is a series of induction coils which are described as "jointless section" owing to the principle adopted for the winding. The transformer or interrupterless machine also figures in the list, and there are various interrupters of well-known types, as well as portable accumulators for use where no electrical supply is available, and motor generators for supplying direct current where the mains give an alternating supply. This range of apparatus, together with switchboards mounted on trolleys or otherwise, may be seen in demonstration at the firm's showrooms in Queen Victoria Street, London.

In these days of high building costs, the value and cheapness of wooden buildings—for example, bungalows, motor-car houses, poultry houses, is often overlooked. The new catalogue of Messrs. T. Bath and Co., 18, Savoy Street, is therefore worthy of reference.

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 33, 35, 37, 38, 39, and 40 of our advertisement columns, and advertisements as to partnerships, assistantships, and locum tenencies at pages 34 and 35.

THE appointments of certifying surgeons at Arundel (Sussex) and Long Buckby (Northampton) are vacant.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Six lines and under	0 9 0
Each additional line...	0 1 6
Whole single column (three columns to page) 7 10 0
Half single column	3 15 0
Half page	10 0 0
Whole page	20 0 0

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Tuesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive post-
resistant letters addressed either in initials or numbers.

EPITOME OF CURRENT MEDICAL LITERATURE.

MEDICINE.

71. Chronic Cyanosis.

ZAGARI (*Ref. Med.*, August 7th, 1920) reports two cases of cyanosis of the extremities unassociated with cardiac, renal, or nervous disease. The first was that of a man aged 20 who suffered from paraesthesia and analgesia of the feet and hands, which were oedematous, and became violet after immersion in cold water or exposure to cold, pallid when raised. His general condition was good, there was no cardiac or respiratory disease. The blood pressure varied from 126 to 140 mm. Hg. There was no evidence of nervous disease and no sign of acromegaly. The second patient was a man aged 44. For six months he had noticed uneasy sensations in the hands, made worse by exposure to cold; four months later similar feelings affected the face and lower extremities, and the hands became a dusky violet and increased in size. There was no headache, but a few hard painful nodules appeared on the scalp. There was some degree of sexual impotence. The blood pressure was rather low and the pulse slow (50 to 54). The sella turcica did not appear enlarged; the Wassermann reaction was negative. The face was peculiarly fixed, giving a mask-like appearance, the hands were cold. The bones of the hands were slightly enlarged and thickened. The skin was usually dry, but there were occasional attacks of sweating. In neither case was there any sign of congenital, cardiac, or capillary disease, nor of syringomyelia, hysteria, or myxoedema. In the second case certain points suggested a connexion with acromegaly. Probably both cases were due to vaso-
was no destruction of tissue such
disease. The author refers to
by Cassier and assumed by him
to be due to some central vasomotor neurosis associated
with endocrine changes.

72. Digitalis and Ouabain.

VOLZ (*Ref. Med.*, July 31st, 1920) says that digitalis is a "diastolic drug," and acts chiefly by altering the rhythm of the heart and disturbing the intracardiac conductivity, it increases the myocardial excitability, but has little or no influence directly on cardiac tone. In his view the particular nature of the valvular lesion to be treated—aortic or mitral—is not of much consequence, the chief point to be considered is irregularity of rhythm. It is in cases of this condition that digitalis is especially useful, but it must be given in adequate doses, small doses are useless, as the effect we wish to produce is a kind of heart block. There are cases, however, where digitalis given in full doses does no good, and in some of these strophanthin has been found particularly efficacious. Strophanthin, unlike digitalis, is a heart tonic, but it is rather an uncertain drug, the author has been using ouabain, a glucoside with properties akin to those of strophanthin, and this has given excellent results where digitalis has failed. It is especially useful in acute dilatation of the heart. The author gives it intravenously in $\frac{1}{2}$ mg. doses, after ouabain has been administered and produced its effect, digitalis will often prove efficacious to continue with.

73. Arsenical Paralysis due to Neo-salvarsan

GOVARTS (*Le Scalpel*, October 9th, 1920) records the case of a man, aged 23, who, after nine injections of neo-salvarsan, developed characteristic arsenical exfoliative dermatitis. Two months later, when the lesions were cured, another injection of neo-salvarsan was given, and a more violent and prolonged attack of arsenical dermatitis supervened, followed by paralysis of the extensor muscles of all four limbs. The paralysis persisted for about ten days and then progressively diminished, so that when the patient was discharged from hospital his gait was normal, though the knee jerks and ankle jerks were still absent.

74. Treatment of Whooping-cough

LIEBER (*Mon. Hb. Wch.*, November 25th, 1920) has treated twenty-five cases of pertussis by painting the throat every two days with a 2 per cent. watery solution of silver nitrate, as recommended by Ochsens. In the great majority of cases good results were obtained. He found that the paroxysmal stage was considerably shortened;

the paroxysms at night were diminished, and long standing attacks were rapidly cured. He attributes the success of the treatment not to a specific bactericidal action, as Ochsens maintains, but to suggestion. The method should be reserved for older children without a neuropathic disposition, in whom the attacks have lasted a considerable time.

75. Heliotherapy in Secondary Syphilis.

RASCH (*Lg. skrift for Læger*, November 25th, 1920) notes that while heliotherapy is a generally recognized and valued remedy in tuberculosis, its possibilities have hardly been discussed, far less tested, in syphilis. Apart from publications dealing with syphilitic leucoderma and its relation to sunlight, little or nothing has been written about the action of sunlight on the *Spirochaeta pallida* and its manifestations. As an incentive to experimental investigations, the author records a case in which a secondary eruption was universal except on those parts of the body which had been exposed to the sun. The patient was a girl of 19, whose disease had been neglected. As the illustrations published by the author show, the eruption ceased abruptly at a line corresponding with the upper limits of her low cut bodice. It appeared that the marked pigmentation of the upper part of her chest and back was due to her having had to wear an invalid about in the sun daily throughout the previous summer.

76. Vaccine Treatment of Empyema.

DELEZ (*Bull. et mem. Soc. de Chir.*, December 14th, 1920) records the case of a child, aged 2, with a staphylococcal empyema following pneumonia, in whom the effusion filled almost the whole of the left side of the thorax. Within sixty days, however, after eight injections of antistaphylococcal vaccine, all the effusion had subsided without operation and the patient had gained more than a kilogram in weight. Four months later it was impossible to tell by percussion or auscultation on which side the empyema had been situated, and on x-ray examination the left side of the thorax presented a normal appearance.

77. Bronchiolitis due to Irritant Gas

DE CONCILIS (*Ref. Med.*, September 4th, 1920), describing the acute symptoms which follow the inhalation of irritating gases, says they may be divided into three stages. The first stage is characterized by severe reflex phenomena—for example, sense of suffocation or of constriction of the fauces, asthma, obstinate cough, and in some cases death by syncope. The dyspnoea is mainly expiratory and irregular, with frequent exacerbations, cyanosis, subcutaneous emphysema, dilatation of the right side of the heart, and slowing of the pulse are often present. The obstruction to the flow of blood in the veins of the head and neck may cause slight exophthalmos and increase in the circumference of the neck. The rales present are sonorous and the percussion note is resonant. Expectoration is frothy and blood stained. The temperature is usually normal. This first stage lasts from one to two weeks. The second period is marked by a rather sudden cessation of the symptoms, due to reduction in the swelling of the mucous membrane. In the third period the symptoms of asphyxia reappear in consequence of cicatrization of the small bronchioles. Some of the cases were wrongly diagnosed asiliary tuberculosis. Pathologically the lesion produced by gas is a necrosis with consecutive connective tissue proliferation in the bronchioles.

78. Arterio-sclerosis and Dementia Praecox.

LIE (*Nord. Vag. for Lægerenskab*, November, 1920) has attempted by the following investigations to answer the question does arterio-sclerosis play a part in the genesis of mental disease, notably dementia praecox. At Dikemark Asylum 112 cases of dementia praecox (70 males, 42 females), all under the age of 35, were admitted within a period of three years. Six of these cases were rejected for investigation because the diagnoses were in doubt. Among the remaining 106 there were 41, or 38.7 per cent. (37 males, 4 females), whose arteries showed more or less definite thickening. The difference in the frequency of arterio-sclerosis in males and females was striking, and it was noted that practically all the males with arterio-sclerosis were manual labourers. Alcohol

and syphilis were seldom noted in the histories, but all the males were more or less addicted to tobacco, most having begun to use it under the age of 15; 2 had begun even before the age of 6. The author commits himself to no definite correlation of arterio-sclerosis with the onset of dementia praecox, but he suggests that the frequency of arterio-sclerosis among the male subjects of dementia praecox deserves further study.

79. False Perforation in Paratyphoid B Fever.

OLLIVIER (*Journ. de Méd. et de Chir. Prat.*, September 25th, 1920) reports an example of the occurrence in paratyphoid B fever of a syndrome similar to that met with in typhoid and called by Rochard "false perforation." In such cases laparotomy (which is followed by an immediate disappearance of the symptoms) shows only a few adhesions, slight redness and congestion, a dilated colon full of faeces, or no lesions at all as in Ollivier's case. A painful reflex of mesenteric origin has been suggested as the explanation of the condition.

80. Cerebral Diplegia and Little's Disease.

ACCORDING to VAGLIO (*La Pediatria*, September 15th, 1920), who records eighteen illustrative cases, between spastic hemiplegia, double hemiplegia and cerebral diplegia, there is a difference of degree only. All three constantly show a multimorphy of symptoms, a variability of lesions both as regards their character and extent, and a plurality of causes. The prevalence of contractures over paralysis, or vice versa, is not, in Vaglio's opinion, sufficient to produce fundamental differences.

SURGERY.

81. Acute Primary Perichondritis of the Larynx.

ACCORDING to LAVIELLE (*Rev. de laryng., d'otol., et de rhinol.*, October 30th, 1920), two forms of this condition may be described—namely, a circumscribed form and a diffuse form. The circumscribed form, of which an example is recorded in a woman, aged 55, successfully treated by operation, is characterized by pain and cough, without any difficulty of breathing. The neck is increased in size, movement of the head is difficult, and examination of the region is very painful. Laryngoscopy shows redness and swelling of the vocal cords. There is considerable general disturbance. The prognosis is good, recovery taking place with a loss of a portion of the thyroid cartilage. In the diffuse form pain is the principal symptom, swallowing is difficult, and there is marked embarrassment of respiration. Laryngoscopy, which is difficult to perform, shows a diffuse redness and more or less pronounced swelling of the arytenoids and vocal cords. Suppuration, contrary to what occurs in the first form, is exceptional. The general condition is very grave, and the prognosis is almost always extremely grave.

82. Subretinal Cysticercosis.

ACCORDING to FILLATT (*Wien. Klin. Woch.*, October 14th, 1920), who records a case of successful removal in a man aged 29, subretinal cysticercosis was a very rare condition before the war. Thus in Sattler's eye clinic at Leipzig only two examples occurred among 90,000 cases, and in Herrenschwand's eye clinic at Innsbruck in the sixteen years prior to the war not a single case occurred. Nor were any examples met with by Hirschberg among 65,000 cases from 1895 to 1902, nor by Silex in the Berlin Polyclinic during the ten years preceding the war. Since 1900 only two instances have been seen in Vienna among 250,000 eye cases. The greater frequency of subretinal cysticercosis since the war is due to bad sanitary conditions, and the inability to cook meat long enough during a war of movement. The cases have occurred exclusively in soldiers. Two cases were reported by Carsten in 1916 and 1917, two by Herrenschwand in the Innsbruck clinic, four by Uhtoff in the Breslau clinic, and one by Schick in Halle.

83. The Importance of Wassermann's Reaction in Institutions for Scrofula.

HERTZ (*Ugeskrift for Læger*, October 21st, 1920), who has carried out systematic Wassermann tests at the coast hospital at Refsnaes in Denmark for the past ten years, finds this test of great service. It was positive in 2.5 per cent. of his 1,610 cases, and it enabled him to institute rapidly curative specific treatment in many cases which

for years had received no benefit from antituberculous treatment in various hospitals and sanatoriums. Among the cases of arthritis syphilis of the knee-joint predominated, and among the ocular diseases dacryocystitis, sometimes with ulceration, was so common that the author has come to suspect syphilis in every such case. But among several hundred cases of spina ventosa he has found syphilis only in two, although Calot and Menard maintain that syphilis is responsible for 50 per cent. of all cases of this condition.

84. Strychnine in Post-operative Atony of the Stomach.

DISCUSSING the mechanism and treatment of post-operative dilatation of the stomach, HANSEN (*Ugeskrift for Læger*, November 18th, 1920) recommends the injection of strychnine, which he found remarkably effective in the following case: A man, aged 21, was operated on under ether anaesthesia for ulcer of the pylorus; a gastro-enterostomy was performed. Eight days later vomiting set in, and was so refractory to treatment, which included repeated aspiration of the contents of the stomach and injections of eserine, that the abdomen was again opened. But no kink or other cause for the continued vomiting could be found, and the abdomen was again closed. The vomiting and other signs of gastric atony persisted in spite of large quantities of bile-stained fluid being withdrawn three times a day through the stomach tube. When this condition had lasted eighteen days after the second operation, and there was no sign of improvement, 1 mg. of strychnine was injected with almost immediate effect. The vomiting ceased, the diuresis increased, and recovery followed.

85. A New Anaesthetic.

BARDE (*Bull. Soc. de Théor.*, November 10th, 1920) describes a new anaesthetic named diethyl-diallyl-barbiturate of diethylamine, which is prepared by a combination of diethylbarbituric acid (or veronal) and diallylbarbituric acid with diethylamine. Given intravenously it produces a narcosis varying in duration from twenty-four to forty-eight or even sixty hours. It is regarded as suitable for operations in which complete muscular relaxation is not required. The claim is made that it forms a valuable adjuvant to general anaesthesia, as it does away with the stage of excitement and renders only a very small quantity of anaesthetic necessary.

86. Removal of Astragalus in Paralytic Feet.

THE end-results in 217 cases of infantile paralysis in which the astragalus was removed for a paralytic condition of the foot, resulting in lateral instability and various other deformities, are given by SEVER (*Journ. Amer. Med. Assoc.*, October 30th, 1920). Whitman's operation was performed on 217 feet in these cases by eight different surgeons; the feet varied from those completely paralysed to those in which only one muscle was weak or gone. In many cases the operation failed to restore either symmetry or stability. As a result of this analysis Sever feels that astragalectomy is not an operation to be advised for any foot showing lateral instability as a result of the paralysis of one muscle group alone. The lateral instability at the ankle may be averted, but more subsequent deformity may develop. Astragalectomy is as good an operation as any in feet which are flail, or those which have only one muscle group left. In the presence of toe flexors, varus is likely to develop later and lead to a bad weight-bearing position. The best results are found in feet in which there was good muscle power before operation, and when after operation there resulted good motion between the tibia and os calcis, and good weight-bearing positions of the foot. The operation will not cure a limp, or even improve one as a rule; it should be performed on older children in selected cases.

87. Dupuytren's Contraction.

ALI KROGIUS (*Finska Läkarsällskapets Handlingar*, September and October, 1920) has investigated the 22 cases of Dupuytren's contraction observed at his hospital since 1888. In 12 the disease was bilateral, and of the unilateral cases 7 were right-handed. All the same, the author can find little or no connexion between heavy manual labour and the development of this disease, and among his patients were officials, business men, and a soldier. Ten per cent. of the professors of Helsingfors had suffered from this condition, which in 4 cases appeared to be hereditary. Thus, in one family, 16 cases had occurred in four generations, and it appeared from the genealogical table that this hereditary tendency could be transmitted through

healthy women. Of the 22 cases, 18 were males, and the disease developed in more than half the cases before the 40th year. The author's histological examinations in 13 cases have convinced him that the disease is primarily due to the conversion of embryonic islands of muscle cells into fibrous tissue. The histological examination of the palmar aponeurosis of newborn infants showed that, among the bundles of fibrous tissue small islands of striated muscle undergoing conversion into fibrous tissue could be found. On the other hand, the author could never find any sign of inflammation, such as a small celled infiltration. He does not, however, deny the possibility of trauma provoking this condition, but he considers it primarily as a developmental disease due to disorders of growth in the superficial palmar muscles. Much of his paper is concerned with the palmar muscles of various mammals.

88. Famine Osteomalacia.

ACCORDING to CRAYER and SCHIFF (*Rev. med. Suisse rom.*, November, 1920), who report a case in a native of Geneva who had spent her last two years in Russia, the onset of famine osteomalacia is almost always insidious and its course at first regularly progressive. Three forms may be described: (1) Abortive attacks, which are rare. (2) Moderate attacks, in which the loss of power is not complete. (3) Severe attacks, in which the patients are bedridden and their immobility is complete. In the moderate cases there are two principal symptoms—namely, costal pain on pressure on the chest (most marked over the seventh and eighth ribs) and a peculiar cautious and waddling gait, both these symptoms being due to the softening of the skeleton. In the severe form these symptoms are more pronounced. Respiratory movements are sufficient to cause pain in the thorax, walking is impossible, and the sternum is soft and elastic. Pressure is painful on all the bones except the skull. Bony deformities appear, especially kyphosis in the dorsal and lumbar region, and fractures, complete or incomplete, occur, usually both in the extremities and the ribs. The renal functions are not affected. Famine osteomalacia is distinguished from ordinary osteomalacia by its rapid progress and the more uniform affection of the skeleton, the pelvis being most markedly affected in ordinary osteomalacia. Lastly, famine osteomalacia is rapidly improved by calcium and phosphorus medication, which is useless in ordinary osteomalacia. Most writers are agreed in attributing famine osteomalacia to a plural glandular insufficiency due to inadequate nourishment.

OBSTETRICS AND GYNAECOLOGY.

89. Cervico-vaginal Fistulae

RECHT (*Zentralbl. f. Gynäkol.*, September 25th, 1920) records two cases of cervico vaginal fistulae tunnelling the posterior lip of the cervix. The first case was that of a woman of 19, to whom, one week after a missed period, an abortionist had given injections through a gum elastic catheter, previously dipped in an antiseptic solution. This procedure was repeated almost daily for some weeks, eventually, when the pregnancy had continued to the beginning of the fourth month, a severe haemorrhage ensued. The external os was found to admit one finger, in the posterior portion of the cervix was a perforation admitting two fingers and leading into the cervical canal. The foetus was 18 cm. long, an arm had prolapsed through the fistula and lay in the vagina, the fistula and the cervical canal were occupied by the remaining parts. The embryo having been removed, convalescence was uneventful, but the fistula persisted. The second case also was due to criminal abortion, attained in this case after fewer injections and in the second month of pregnancy. In both cases the vaginal fornices were otherwise unimpaired. According to Neugebauer, who has recorded thirteen cases falling in the first and four in the second group, cervico vaginal fistula of the posterior lip of the cervix may be due to (1) obstetric trauma, (2) criminal abortion, or (3) pathological conditions such as tuberculosis, diphtheria, syphilis, or carcinoma.

GO. GRAMANN (*D. M. Woch.*, June 24th, 1920) records a case of cervico vaginal fistula which occurred in a primipara aged 22, who aborted at the fourth month. He attributes the complication as being due to exaggerated uterine anteversion, and to rigidity of a somewhat hypoplastic cervix and os externum.

91. Intrauterine Therapy for Uterine Infection.

VIGNES (*Gynec. et Obstet.*, 1920, 11, 3) remarks that intra-uterine treatment, widely recommended at the close of last century for puerperal infection, has been renounced by many obstetricians—partly as a result of extended clinical obstetrical experience, and partly because war surgery has shown that wounds infected by streptococci are particularly resistant to local treatment, of which the only efficacious method is early excision. Curettage does not necessarily remove all infected foci; it is usually followed by a rise of temperature and not infrequently by a serious and prolonged aggravation of the symptoms. By curettage the lymphocytic barrier is broken down; parametritis and thrombo phlebitis are relatively more frequent after curettage. Digital scraping, according to de Lee, Couvelaire, and Vignes, is equally as objectionable as instrumental curettage. Vignes, from a comparison of cases of puerperal infection in which intrauterine treatment has and has not been used, concludes that the gravity and mortality of the malady are almost doubled by intervention. In cases of uterine infection following labour at term—cases of partial placental retention excepted—it is dangerous and useless, he thinks, to employ intrauterine treatment after the first week. Intra-uterine applications—for example, of alcohol or iodoforn—are unjustifiable, these cannot kill the micro organisms without killing the tissue cells, and some of them kill the tissue cells without killing the micro organisms. Douching is the least objectionable form of intrauterine therapy, but may be followed by untoward primary or remote effects; it is usually without effect on the course of the infection, but may be justifiable—provided that it be not performed more than once—in cases of retention of loose fragments of the membranes or of clots.

92. Abdominal Hysterectomy for Puerperal Infections.

ACCORDING to LE JEMTEL (*L'Année med. de Caen*, March, 1920) hysterectomy may sometimes be practised with benefit in cases of puerperal infection; it may lead to good results even in cases where there is a blood infection. Four cases are recorded, with three cures. Two of the successful cases were of placental retention, operation being performed on the second and fifteenth days respectively.

93. Tuberculosis of the Cervix.

VERDELET and DAVIGNEZ (*Journ. de Med. de Bordeaux*, September 25th, 1920) record the case of an unmarried woman, aged 25, who had never menstruated, but for about a year had been becoming progressively thinner and had had a pale discharge. The cervix was small, and the os could not be felt nor seen, on the right lip there was a soft polypus 5 or 6 mm. long, and almost insensitive. The cervix also showed the presence of multiple small clean cut ulcerations. The polypus was removed, and the region of its insertion as well as the ulcers cauterized. Microscopically the polypus contained numerous glandular tubules between which tubercles could be seen.

94. An Unusual Case of Hydatidiform Mole.

VIOLLET (*Gynec. et Obstet.*, 1920, 11, 1, and *L'Avenir med.*, 1920) records the case of a woman four and a half months pregnant, who had had haemorrhage for two months and a half. The size of the uterus was consistent with the duration of the pregnancy; through the dilated external os a soft mass could be palpated within the cervical canal. Cure was effected by vaginal Caesarean section. The uterus was found to contain no foetal parts, the whole of the mass extracted consisted of placental tissue showing long standing haemorrhages and infarcts, and here and there a few vesicles, of which some were of spherical shape and about half the diameter of a lentil, and others were of the shape and size of a date stone.

95. Dystocia Due to Carcinoma of the Foetal Kidney

PORTER and CARTER (*Am. Journ. of Diseases of Children*, October, 1920) record the case of a 6 para, aged 35, in whom at term the head, shoulders, and arms of the child were spontaneously delivered, but the remainder of the body could not be brought down. The patient being anesthetized, an incision was made into the abdomen of the dead foetus—a sufficient amount of viable tumour tissue was removed to permit the remaining parts to be born. The tumour, which was almost twice the size of the foetal head, was proved microscopically to be a round-celled sarcoma of the kidney. The course of the pregnancy had presented no unusual features.

86. Influence of Forceps on the Subsequent Physical and Mental Development of the Child.

ENGELKENS (*Nederl. Tijdschr. v. Geneesk.*, October 16th, 1920) made an inquiry into the subsequent history of 448 children who had been delivered by forceps in the Amsterdam and Groningen Obstetrical Clinics between 1900 and 1914. Information was obtained concerning 232 only. In 105 low forceps, and in 39 high forceps, had been used; in 82 Lange's method, and in 6 Scanzoni's method had been employed. The result of the inquiry was that the forceps was thought to have been responsible for one case of epilepsy and possibly for one of imbecility among the 232 cases. It was remarkable that no instance of spastic diplegia was found, although Little and many after him have attributed the condition entirely to an abnormal birth. Engelkens concludes that the influence of forceps extraction on the mental and physical functions of the child is exceedingly slight.

97. Early Recognition of Uterine Cancer.

JACOBS (*Gynec. et Obstet.*, 1920, i. 6) expressed to the Belgian Gynaecological and Obstetrical Society the opinion that the most hopeful means of diminishing the mortality from uterine cancer lies in the dissemination among the laity, as well as among doctors, chemists, and midwives, of a greater knowledge of its earliest symptoms. Among 98 patients suffering from this disease he found that those who deferred the taking of medical advice for from twelve to twenty-four months numbered 37; 5 patients first consulted the doctor nine to eleven months after the appearance of the first symptoms; 15 eight months after; 4 six months after; 4 four months after; 14 three months after; 7 two months after; and 9 one month after. Nine only sought advice during the first month; 3 consulted the doctor at once. The cause of the procrastination was in 72 cases carelessness and ignorance; in 8 cases fear; in 6 cases poverty; and in 3 cases shame. In 26 cases advice was first sought from a specialist, in 31 from the family doctor, in 6 from a midwife, in 14 from a chemist, in 2 from totally ignorant persons. In 19 cases the seeking of advice was not followed by vaginal examination. Of these 98 cases, 72 when first seen by the author had reached the inoperable stage.

PATHOLOGY.**98. A New Serum Reaction in Syphilis.**

GATÉ and PAPACOSTAS (*C. R. Soc. Biologie*, November 20th, 1920), accidentally discovered a new and simple method for examining the serum in the diagnosis of syphilis. They had been accustomed to pool their positively reacting serums, the mixture serving to control the fixative power of the antigens, and also to pool the negatively reacting serums in order to fix the complement-absorbing unit in the Wassermann reaction. These serums were preserved as usual in an ice-chest, but owing to an explosion occurring in the laboratory they were forced temporarily to use some other means of keeping the serums uncontaminated. For this purpose they added formalin, but were astonished to find on the following day that the mixture of serums reacting positively in the Wassermann test had coagulated to such an extent that the tube could be turned upside down without disturbing the clot. The mixture of negative serums, on the other hand, remained perfectly fluid. This observation led them to study the phenomena more closely, and on a larger scale. The test as now evolved consists merely in placing with a pipette 1 c.cm. of clear serum at the bottom of a test tube, adding two drops of commercial formalin, shaking to obtain a good mixture, and leaving the tubes stoppered with cotton-wool at the room temperature for twenty-four to thirty hours. The reading of the reaction is easy: in positive reactions the mixture becomes more or less solid, clear, and jelly-like; in negative reactions it remains perfectly fluid. In this way they have tested over 400 serums, and compared the results with those obtained in the Wassermann reaction. Mixtures of positive Wassermann serums always give positive formalin reactions, and mixtures of negative Wassermann serums always give negative formalin reactions. In separate cases the results of the Wassermann reaction and this formol-gel reaction accord in 85 per cent. of instances. They state that where the two reactions disagreed they were unable to discover which was the more accurate, as the true diagnosis in these cases was unknown. However, in certain cases, such as early syphilis, clinically certain, where the Wassermann reaction failed, the formol-gel reaction gave positive results.

Preliminary inactivation of the serum is unnecessary, nor does it modify the reaction in any way to incubate the mixtures.

99. Acquired Immunity in Influenza.

DOPTER (*Paris méd.*, October 23rd, 1920) has collected a large quantity of epidemiological and experimental evidence showing definitely the acquisition of immunity after a first attack of influenza. This applies only to influenza itself, and not to its complications, which, during an epidemic, may be contagious in themselves without any influenzal substratum. Although immunity does exist, it is not absolute, as Burridge and Cummins observed second attacks in 20 to 23 per cent. of their cases. The duration of the immunity, according to observations made by Malone in India, is at least nine months, and possibly longer.

100. Parasitic Amoeba in the Tonsils.

TIBALDI (*Annali d'Igiene*, October, 1920) draws attention to a new species of amoeba found by him in the tonsils and called *Entamoeba macrohyalina*. Two kinds of entamoebae may be found in the tonsil: (1) *Entamoeba* commonly found in the mouth and tonsil; (2) *Entamoeba macrohyalina*, which is much more rarely detected and prefers the crypts of the tonsils. Owing to paucity of material, the author is unable to express an opinion as to the pathological importance of these entamoebae. Both amoebae are fully described and coloured reproductions of their microscopic appearances are given.

101. Pathology of Congenital Laryngeal Stridor.

WERNSTEDT (*Hygiea*, October 16th, 1920) has examined post mortem two cases of laryngeal stridor in infants dying of intercurrent diseases. The first case was that of a female infant who had suffered from laryngeal stridor since birth. She died of whooping-cough when 9 months old. A close comparison of her larynx with the corresponding organs of eleven other infants showed practically no deviation from the normal, apart from a negligible narrowing of the larynx in the sagittal plane. The second case was that of a female infant, who had suffered from laryngeal stridor since birth, and who died of bronchopneumonia. The larynx in this case corresponded in every respect with the larynges of six "control" infants of the same age, with the important exception that the aditus laryngis formed an abnormally narrow, slit-like opening owing to the exceptionally close proximity to each other of its component parts. The author suggests that these cases may be taken as types of two distinct classes: In the one the stridor is a functional disturbance—a disturbance of co-ordination; in the other definite anatomical anomalies, such as stenosis of the aditus laryngis, give rise to the stridor.

102. Rapid Preparation of Polychrome Methylene Blue Stain.

THIBAUT (*Journ. Amer. Med. Assoc.*, November 20th, 1920) describes the preparation of polychrome methylene blue (used for staining fresh tissues) by a method which does not necessitate waiting for six days, or more, till the stain ripens. One part of methylene blue and one part of potassium carbonate to 100 parts of water are boiled in a flask for fifteen minutes and allowed to cool; after filtering, the stain may be used at once. The stain keeps well; its efficiency may be increased by the use of a mounting fluid containing resorcin (75 parts of water, 8 of sodium chloride, 2 of resorcin, and 25 of glycerin).

103. The Presence of Spirochaetes in Lymphatic Glands.

FRÜHWALD (*Wien. klin. Woch.*, November 11th, 1920) carried out 89 punctures of the lymph glands in 83 syphilitic patients to determine the presence of the *Spirochaeta pallida*, with the following results: Of 24 patients in the primary stage, 20 showed spirochaetes in the regional lymphatic glands. Of 18 patients at the beginning of the secondary stage, only 7 showed spirochaetes in the puncture fluid. Of 27 cases in the late secondary stage, 20 were negative; 4 cases in the tertiary stage were also negative. Of 14 cases in the latent stage, 3 were positive and 11 negative. It is thus obvious that in the early stage of syphilis the *Spirochaeta pallida* is very frequently present in the regional lymph glands, and even in the late secondary stage it is often found, though with diminished frequency. The duration of the disease in such late secondary cases was from four months to two years. In the latent stage spirochaetes were found as late as the third year of the disease.

Polyglandin

Indicated in Hysteria & Uterine Disorders. Also in Neurasthenia, Melancholia & Sexual Neuroses

TREATMENT by pluriglandular extracts favours general secretory activity, and many cases of apparently monoglandular deficiency benefit more by mixed hormone treatment than by the administration of the extract from a single isolated unit of the endocrinous gland system. It is now recognised that normal metabolism depends upon the hormone balance being maintained, and that the functions of the endocrine organs are plural rather than singular. The administration of gland substances must not be regarded from the narrow standpoint of replacing a deficient secretion, but rather as stimulating particular organs to greater activity for a longer or shorter time. "Polyglandin" enhances muscular, mental and nervous activity, and is a general stimulant to the cardio-vascular system.

RADIUM-THERAPY.

A safe, economical and convenient form of radio-active therapy in everyday practice.

MESOTHORIUM.

Mesothorium is a radio-active substance derived from Thorium discovered simultaneously by Mme. CURIE in France and Professor HAHN in Germany: it goes through a series of successive transformations, each one being accompanied by emission of radiations similar to those of radium and called α , β and γ . The α and β rays have particles laden with electricity positive in the case of α , negative in the case of β ; γ rays are similar to X-rays.

These radiations were first used in therapeutics in the form of very expensive apparatus. They were based on a partial or total utilisation of the rayonnant power produced by large quantities of radio-active substances and were particularly used for the treatment of cancer and diseases of the skin, prostate, and genito-urinary organs.

Mesothorium and Radium have been experimented with concurrently, and the superiority of Mesothorium has been maintained.

PHYSIOLOGICAL ACTION OF MESOTHORIUM.

Mesothorium, introduced into the organism by injections, acts on the respiratory and circulatory systems, the digestive tract, and eliminations.

If the respiratory phenomena are not much influenced in normal health subjects, in cardiac dyspnoea the pulmonary capacity is amplified and the utilization of oxygen increased (30% in some cases).

Mesothorium salts have a very marked effect on circulation, as shown by the following phenomena: Lessening of the blood-pressure, which continues after total elimination of the Thorium emanation and of its products of disintegration, slowing of the pulse. In fact, they bring back calm and regularity in the circulatory system and give the cardiac muscles a rest.

Besides, the Thorium emanation is localised for the greatest part in the bone-marrow, whose hematopoietic function is activated with increase of the red corpuscles and a proportion of Hemoglobin (with lessening of the white corpuscles in leucemia).

Its action on the digestive tract consists chiefly in a remarkable and persistent increase of appetite, even long after the treatment has been discontinued. A definite explanation of this phenomenon has not yet been arrived at, it is only known that Radium destroys ferments, whilst Mesothorium leaves them with all their activity.

Lastly, from the point of view of elimination the most remarkable fact is the intensive discharge of uric acid observed in healthy as well as in gouty and rheumatic patients.

The injections may be replaced by

MESOTHINE TABLETS

when improvement has set in and it is only a question of keeping the organism under the influence of Mesothorium in order to accentuate the good results of the initial treatment and to complete it.

The use of Radium in this way had serious disadvantages.

DERMATHORIUM.

Mesothorium Bromide Ointment.

Skin Diseases and Cutaneous Affections treated by the complete rayonnant power.

Dermathorium owes its therapeutic successes to the presence of a well standardised dose of Mesothorium.

Telegrams: "AMPSALA AS, LONDON."

The INCREASED PRICE OF PETROL

NEED NOT ADD TO THE COST OF RUNNING A CAR.
Private Motorists can EVEN RUN THEIR CARS AT
CONSIDERABLY LESS THAN HITHERTO, if they
become Members of

Tyres, Lubricants, and
General Motoring Re-
quirements delivered
carriage paid in the
United Kingdom at co-
operative prices.

Large stocks held, and
 a splendid service given.

Motor Insurance—the
 best policies at reduced
 premiums.

NEW CARS in Stock;
 several in stock for immediate delivery.

NOTE.—The Society has never charged a premium.

USED CARS. A fine selection received for sale from Members.

REPAIRS AND OVERHAULS at the Society's own Works.

The Society—which is a genuine Members' Co-operative Society—is splendidly organised, and, apart from other advantages, the money saved by its members is very considerable.

The Society is prepared to contract to run a Member's Own Car, providing Chauffeur, Petrol, Tyres, etc., etc., for a low annual and inclusive price, and return the member any certified net profit earned. All private motorists should call or write for a Prospectus and join at once.

An Address

ON THE

APPLICATION OF THE PROFESSIONAL
LESSONS OF THE WAR TO
CIVIL WORK.*

BY

SIR HENRY M. W. GRAY, K.B.E., C.D., C.M.G.,
F.R.C.S. EDIN.,

SURGEON TO ABERDEEN ROYAL INFIRMARY.

THE subject of my discourse is one with very many sides to it, and can be appreciated fully probably only by those who saw service under the most varying conditions during the late war. I have no doubt that many of you have interested yourselves already in some of the things of which I shall speak. I crave the forbearance of specialists in medical politics, but at the same time I hope that I may be able to interest every one in some measure. In an educational centre like Dundee the results of teaching, especially such as were revealed under the stress and stimulus of war, when the minds of men were strung to a high pitch, must always be of surpassing interest. It is really the study of these results and a desire to help in improvement which has led to this address. That there is room for improvement in medical education and in facilities for work in civil life was, I am sure, appreciated by us all when we were face to face with the difficulties of war work. I am equally sure that we were not troubled with the big aspects of things so much as by the working out and application of details, without which big things were impossible. The well trained man pays attention to details. It is only the exceptionally capable man who in later life can surmount shortcomings of education and compete successfully with his better trained fellows. Judging from my experience in the war, I claim this power for the average medical graduate of Scotland, and on that account I venture to refer to the disadvantages of his present day education in a somewhat forcible way. In saying that, with a better education, his prowess in the arenas of the world would be far more striking, I acknowledge again that I belong to the ultimate division in the Sassnach classification of those north of the Tweed—the Scotsman, the damned Scotsman, and the Aberdonian!

From the outset I wish you to keep in mind the fact that the problems of treatment, both preventive and curative, are virtually the same for the civilian at home as for the soldier in the field, and differ only in the urgency of appeal to our sentiments and to our best efforts. The honest civilian worker, whether of high or of low degree, should be regarded as doing equal service for his country under the conditions of peace as the soldier in war, although the latter, in the strenuous and dangerous conditions of the battlefield, appeals to our emotions in greater degree. The civilian worker is a combatant in the nation's fight for existence, and as such is valuable to the nation in proportion to his activities, and deserves as great consideration as the soldier when he is disabled. Sentiment has not, unfortunately, hitherto stirred the nation to proportionate effort on his behalf.

Civilian Need in Peace.

It has required the stimulus of a ghastly war to produce unprecedented efforts on behalf of the disabled soldier. It is to be hoped that equally strenuous efforts on behalf of the civilian will be forthcoming, but meantime it is regrettable that apparently, as soon as the war is over, the nation should again become apathetic. Instead of there being a general clamour for the very best possible treatment for the civilian worker, and for the provision of the best possible conditions and other facilities for that treatment, voices are being raised only here and there, officially or unofficially, in an attempt to maintain in civil life the high standard which was striven for and achieved by many during the war.

Of course there are great Government schemes in the making which aim at the organization of the medical service of the country, but these were being promulgated

before the war, and one cannot judge of them until they have been tried. My remarks apply especially to the everyday work of the medical man, be he general practitioner or specialist; but you will, I am sure, appreciate the necessity for having adequate organization to regulate such work, although, like myself, you may not be convinced that a State medical service will be altogether a good thing for the patient. Service controlled by "red tape" has its disadvantages as well as its advantages.

*Improvements in Military Medical Work
in France.*

I have said that the stimulus of a ghastly war produced unprecedented efforts on behalf of the wounded soldier, but we cannot blind ourselves to the fact that these efforts fell considerably short of the ideal. In my position as a consultant surgeon in France I could well appreciate the difficulties which stood in the way there of attainment of the ideal, but the influences which led to the vast improvement in the treatment of the sick and wounded soldiers were also apparent, and some of them may be gleaned from the remarks I am about to make. I cannot speak too highly of many individual as well as concerted efforts which resulted in immense improvement in overcoming, and still more in preventing, the terrible sepsis which at first thwarted the efforts of men who had been trained practically entirely under conditions which gave them no experience of the ravages which such sepsis could produce in an incredibly short time. It was not to be wondered at that, at first, adverse criticism of the surgical work in France should be expressed, but I assert, in reply to such criticism, that the critics could not possibly grasp in their minds either what had to be tackled or the conditions under which the work had to be done. The work in these early days was most discouraging in its results, the conditions under which it was carried on were often most unfavourable, and the numbers of wounded were frequently so overwhelming as to fill the stoutest hearts with despair. The wonder to me is, on looking back, not that so many severely wounded men arrived on this side of the Channel in a precarious septic state, but that so many arrived alive.

In reverting to the thesis that the civilian worker should be regarded as a combatant for the nation's welfare, I may be excused if I soliloquize a little on present-day conditions. War is, after all, but a hideous expression of antagonism of communities which has become so concentrated that it gets beyond control. In peace times controlled antagonism is called competition. This when under reasonable and equitable control is good and makes for advance, but when unreasonable and inequitable it really results in war; although of a less obtrusive and apparently milder type, yet, in its less direct and less apparent way, it may have equally disastrous results to the individual or section of the community which goes under. The late world war has been followed by intense resentment on the part of many workers who were in the past unjustly treated—it has driven many patriotic employers to recognize the justice of the claims put forward and to try to meet them. There has arisen a clamour for a reconstruction of relationships which has been, on the one hand, too hastily and too forcibly and unreasonably expressed to enable the balance to be preserved, and has resulted in a chaos which threatens the commercial prosperity and the health of the nation to an incalculable extent. It is a big thing to say, although it is easy to say it, but I believe that the present state of affairs is due to a want of education, and therefore of fulfilment, on the part of employers as well as of employees, of their responsibilities to each other, whether as private individuals or as members of the greatest nation and empire of the world. The application of the remedy is a difficult matter.

Although the members of the medical profession as a whole can, in virtue of their calling, claim in the past to have been probably more altruistic than any other class of workers—except, possibly, that of the allied very noble nursing profession—and although we may have constantly striven for better knowledge of disease, and for its more adequate treatment, yet the war has taught us many lessons which ought to be turned to great advantage to the sick and suffering. In putting my opinions before you I am deeply sensible that they may not agree with those of other men and women whose experience and judgement command attention.

* Address given at the Dundee Branch of the British Medical Association, 15th March 1922.

The rank and file of the medical profession are those splendid general practitioners who do the spade work and the hard fighting, and who count for most, after all, in the medical world, just as the equally splendid infantry soldiers of the line regiments were the men who, after all, counted most in the great war against the Boche and his dupes. But I do not think that the majority of our rank and file are paying enough attention to the application in their daily work of these important lessons which, when properly learned and applied, will help professional work to be better done; more easily done, done with greater satisfaction and happiness to ourselves, and consequently with greater benefit to the patients whom we attend. I mention general practitioners especially, as they form the backbone of the profession, and there must be a sound, efficient, active, well co-ordinated backbone in order that the body may make progress. That is why I think in medical schools like Dundee and Aberdeen, whose function it is especially to produce general practitioners, great care should be taken that those in charge of the training of students be not overtaxed, as I venture to think is occurring just now because of the too large number of students.

It is impossible, under the conditions at present existing, for example, in Aberdeen, to teach clinical work to the average student as it ought to be taught. It is impossible to give that individual attention to each student which clinical teaching demands. The education is perforce imperfect. It is the same meantime all over the country, and, unless the student exerts himself to an unusual extent in his efforts to acquire knowledge, there is a danger that this imperfection may lead to evil results and a temporary degradation of the profession.

I say again that I want you to appreciate that civil work can be compared in all respects to war work. The working class, whether performing skilled or unskilled labour, the so-called middle class with all its widely varying occupations, the upper class—all have their representatives in the navy and army, and although a few people did mighty little in both of these services during the war, the only class which did not have its counterpart is that comprising the idle rich. The citizen, the civilian worker, is to be regarded as a combatant fighting for the nation's welfare, and he should be educated and kept fit for his warfare just as carefully as the soldier. In certain circumstances he may require equally intensive training. As I have indicated already, I do not think he has been sufficiently educated to appreciate his responsibility at this time to put forward all his ability in making up for the waste of war, and there is too little realization of what this is leading to. Students can realize that if they do not work they will not pass examinations which loom in the future. If our nation does not work it will fail in an equal measure. The world's economic state demands an increase in effort all round. There are big proposals being mooted or set agoing to improve conditions of life, but unless the masses of individuals—for example, our general practitioners—bestir themselves to help out these schemes they cannot succeed as they ought.

The civilian must be kept in good health for his work in his particular fighting line, whether in the street, shop, or factory, and if disease or accident should overtake him, he must be made fit again to join his unit as soon as possible. In my experience during the war the surgical arrangements made for the fulfilment of these responsibilities to the soldier were wonderfully and increasingly well developed. The stimulus of war in its ordinary sense is not now present in the minds of the populace to enable us to obtain and maintain equally good and progressive provision for the civilian. It is difficult in this country to make the public see the economic importance of having the very best and fullest provision for the treatment of the sick and wounded civilian combatant. Even yet it is only here and there that the monetary value of good research work is appreciated. All ranks in our profession must join in an increasing effort to educate the people.

Time will not permit me to do more than touch upon the many facts of war work from which we can learn. If my remarks may seem at times somewhat curt and savouring of want of reverence for established customs, I tender a desire for brevity as my excuse, and hope that they will be taken in the spirit in which they are offered; I would add that my criticisms are directed against systems, not against individuals, as I fully realize the

possibility that some might consider that I myself should be included in the criticisms.

In my position as consultant in France, both in a large base area and in an important and oftentimes very active army and later as a consultant in special military surgery in the home service, I had ample opportunity of studying things from many points of view, and the following remarks are the result of my cogitations.

Their Applications in Civil Life.

When a man failed to make good in the army—that is, when he failed to keep pace with the standard set by the majority of other men in similar positions—he was replaced by a more likely man. Under stress of war at the front no post could be maintained for long unless good work was done. Here is our first lesson. Should not the same rule be applied to those in responsible positions, and especially in our schools of learning and in our hospitals? Yet we find that, in some of our universities, men are appointed for life to such positions and remain in office for as long as they alone see fit. Surely this is carrying the principle of "security of tenure" too far! It is absurd that in the most important posts connected with teaching the stimulus of reasonable competition should be excluded during the lifetime of the occupant of the particular appointment concerned. There can surely be found a satisfactory method of control, even although it may require an Act of Parliament to bring it about, whereby, if the standard set by occupants of similar posts elsewhere is not maintained, the delinquent could be deposed from the responsible position which he occupies. I may say that the memory of my experience in the war does not make me tolerant of those who fain would stick to inadequate arrangements merely because they are antiquated.

The stress of war, in that it revealed the necessity for making a combatant efficient again as soon as possible, gradually forced the authorities in control of the purse-strings of the nation to loosen these strings where provision of hospitals and suitable hospital equipment was concerned. I can say that the state of some of the casualty clearing stations—and I speak only of those under my supervision—even within a few miles of the fighting line in France, both in housing and in comfort, as well as in arrangements for professional work, were such, at the period before disorganization was caused by the German advance in March, 1918, that I would have preferred to be treated as a patient in one of them than in many of our hospitals at home. If such perfection was possible under conditions of war at the front, surely it ought to be more than possible under the peaceful conditions of this country. But the question of money and our innate conservatism stand in the way. Purse-strings must be loosened to a greater extent, generosity in subscribing for medical and surgical requirements must be more widespread—those who cannot give in money can give in labour if we are to advance as we ought to. Bigger, broader, more far-seeing ideas must be cultivated. This aspect of affairs is of acute interest in Aberdeen at present in connexion with the development of a big scheme which is being brought forward to improve our hospital service, teaching facilities, and opportunities for clinical study, as well as to conserve expense of working and the time of medical men and students. The scheme includes concentration of the hospitals of the city in one large compound, transference of certain departments of the university to the same site, and, finally, provision of a hostel for senior students, so that they may be on the spot to take advantage of experiences from which meantime they are largely debarred. It seems to me that intending subscribers to such a scheme may hold back on account of the uncertainty which is felt with regard to the future relationship of the Government of the country to hospitals generally. The Government should declare its policy clearly and firmly, and without delay, so that private individuals may know whether they have to undertake the responsibilities, and to what extent.

One of the great developments in connexion with the medical service of the war was that of "team work." The advantages of this were already demonstrated in civil life, notably on a large scale in the Mayo clinic in America, but little more than the talking stage had been reached in this country, and that only in very few centres. It was carried into actual practice, so far as pure surgical work was concerned, at the battle of Arras in April, 1917, and

its success was at once established by the fact that the number of operations then performed in proportion to the number of wounded was largely increased when compared with former battles, and the improvement in results was also very marked. In association with the establishment of surgical teams the whole working of the clearing stations was so organized that all the different departments of these hospitals were more closely linked up, and by the collaboration of the medical officers in charge of these departments the work as a whole was more efficiently and smoothly performed than ever before. Physicians, bacteriologists, skiagraphists, surgeons, administrative officers, nurses, orderlies, stretcher-bearers, cooks—all worked wholeheartedly, and, so to speak, hand in hand as a big team for the general good of the wounded soldier. Antagonism was barred, friendly competition and pride in work were paramount. It was found that the success of any team was proportionate to the driving force of its chief member. While it cannot be said that there is want of collaboration, for example, in such an institution as our Aberdeen Royal Infirmary, and even although there is a tendency to develop the team spirit in some quarters, yet there is a good deal left to be desired. This is not the fault of the medicos concerned, but rather of the conditions of work. I am afraid, however, that I must not discuss this matter further at present, except to say that the appreciation of the value of the system is reflected in the frequency with which the term "team work" is used in our everyday life. Seeing that no single individual can be expected to have accurate knowledge of all branches of his profession, "team work" amongst general practitioners is as desirable as in hospital practice.

Age and Youth.

The most striking phenomenon of the war to my mind was the way in which the young man came to the front. As time passed, positions of great importance became filled with increasing frequency by young men, and I believe that if the war had lasted another year, only a very few old men would have been left in France and Belgium, where the main issue lay, and these would have been old men who had remained young. It was remarkable that as the young men or the young old men got more power into their hands the work was better and more quickly done. It was being shown that there was no room in that strenuous field for the man whose faculties were so inert that he could not accommodate his outlook to, or keep pace with, the rapid developments which had to be made in order to cope with the kaleidoscopic changes occurring in such rapid sequence.

Is it not really exactly the same in civil life? Especially at such times as the present, can the nation afford to have obstructionists, whether passive or active, to what should be a strong stream towards success? A strong stream, when its passage is set in turbulent surroundings, entails eddies and backwaters. There are adornments to such eddies and backwaters which are out of place in mid-stream! It is but rarely that the old man, or the "dud" man, can appreciate the fact that he is getting old or that he is a "dud," and that he should step aside to let the junior or the better man have greater sway, and even if he does appreciate it, he can sometimes succeed far too long by his clever camouflage and much speaking. As I have said, the events of the war showed how well the young man could shoulder responsibility and how rapidly he developed sound judgement, foresight, and adaptability in the management of affairs. In the category of old men, as I have already hinted, I do not include him who, in spite of his seniority, could maintain his zeal, earnestness, and thoroughness when at work, who could tough it with the young men, and who could become young again in his off-times, and even play the fool on occasion with the most skillful of the youngsters. Such a man exerted a tremendous power for good among his younger colleagues. He was looked up to and his opinion and approbation were eagerly sought by them. It is such men whom we should cultivate and continue to honour when they retire to the less turbulent parts of the stream. A great truth, which was revealed to me more strongly than ever before by my experiences in the war, was that by trying to help on the younger men one helped oneself. I believe that I can say truly, and I say it in all humility, that when the young surgeon and his colleagues in France found that I was really "out" to help them in their work to the best of my

ability, they responded with a loyalty and devotion in carrying out suggestions which were most gratifying. Any kudos which accrued to me during my time in France was due to that spirit amongst these young men, and I shall cherish the privilege and honour of having served along with them.

Continuity of the Best Treatment.

The importance of developing means of ascertaining and establishing everywhere the best methods of treatment, and of procuring continuity in treatment was increasingly impressed on everyone as time went on. During prolonged battles, which entailed stupendous, unceasing effort on the part of medical officers, it was impossible that they could keep abreast of the advances in knowledge which were occurring unless special provision were made. It was in this respect that the consultants could perform probably their most important function. They could encourage and direct investigation, and by carrying information from one place to another, by actual demonstration in one hospital or by informal conversations or special lectures in another, by stimulating men to meet and to discuss new problems, and by promoting collaboration between workers in units at the same stages and at different stages of the wounded man's progress, they could exert an enormous influence for good. The institution of consultants at home with the powers of those in the army may probably be resented at this stage of our civil professional development, but I cannot help thinking that the needs of all busy members of our profession are not quite so adequately catered for in this way as they were in France, and as they would have been still more had time allowed the aspirations of the consultants to be applied and developed more fully.

Collaboration between units of the actual fighting area and the casualty clearing stations, between the latter and the hospitals on the lines of communication in France, and between these again and the hospitals at home, practically did not exist until the war was well advanced. Communications from home hospitals or from hospitals down the line were almost entirely in the form of complaints as to the condition of the patients who had previously been treated under circumstances of stress and difficulty such as the complainants could not possibly visualize. On the other hand, medical officers of the more advanced units were rather inclined to despise others in so-called soft billets further removed from the fighting line, and to resent complaints from them, while advice from the same sources was almost equally unacceptable. I need not detail the means which were taken to bring about a better understanding, which was attended with happy results wherever it occurred. It is still too often the case in civil life that the hospital physician or surgeon, or even the student, forgetting the disadvantages under which the general practitioner has in many instances to work, is inclined to scoff at the treatment or mistaken diagnosis, which may have had to be made in a hurry—possibly, for example, in a box bed in a squalid cottage, with a spluttering candle as the sole means of light. On the other hand, does the general practitioner always look with favour on the consultant? Sympathy and collaboration are required as much at home as they were abroad.

Defective Medical Education.

The next point which occurs to me I mention almost with reluctance, but I do so because I realize my own shortcomings. One was very frequently impressed with the wonderful knowledge of obscure signs and often of fantastic theories concerning disease or injuries which was thrust at one, and one ought to have felt oneself to be a very inferior worm, but one took heart again at the thought that such phantasms and the "tall" language in which they were described helped not at all in the practical, life-saving problems which were crying out for solution. It was evident that something had been wrong with medical and surgical education when such theorists were found to be unable to dress wounds or apply bandages or splints efficiently. What some of our friends across the water call "horse-sense" of the majority saved the situation. It is a pity that some specialists who occupy teaching posts forget to impart the rudiments of a subject to the students under their tuition and speak to them of exceptional matters in "high-falutin" language, which is repeated in parrot fashion too often without understanding.

The student ought to be well grounded in the simplest, most common, and most useful things which pertain to the practice of his profession, and be taught to think and act for himself. The curriculum tends to become unduly crowded, and there is no time for consideration of subjects which are better suited for post-graduate study. As I have already pointed out, sensible teachers feel that at this critical period of university education each student must try to work out his own salvation, in view of the fact that owing to the unduly large number of students it is impossible to give that attention to individuals which is desirable. The important problem is how best to stimulate self-help, considering that the spirit of the age is so foreign to such a virtue.

It would appear that collaboration between teachers, with the object of eliminating unessential details which merely clog the minds of their students, is required more than ever. How much is the advice of clinical teachers, as to what is most useful, sought by those who deal with subjects like anatomy, physiology, chemistry or physics? Yet these and certain other subjects of study can only be regarded as preparatory to clinical work, and should therefore be adapted more closely than they are to the requirements of the average medical student.

Evils of Systematic Courses.

I cannot refrain from saying that my experience during the war has led me to object more strenuously than ever to the retention of courses of systematic lectures in the medical curriculum of our Scottish universities. These systematic lectures and the slavish taking of notes are relics of bygone ages which ought to be dispensed with. They were necessary even as late as 50 to 100 years ago, when such excellent textbooks as are extant at the present day were not available to the student. How many of us can honestly say that we retain any useful memory of the often wearisome lectures which we were compelled to attend day after day, during which our minds were distracted by the scrambling efforts of our pencils to keep pace with the lecturer, while our evenings were spent in the endeavour to make sense out of our notes and to supplement them with extracts from books? I think that under modern conditions the ordinary course of systematic lectures is very largely a waste of time both to lecturer and student. The professor should discourse much more on principles, leaving tutorial work in matter of detail to assistants. Especially in surgery, but also in certain other subjects, practical instruction should bulk more largely than it does.

Early Treatment and Transport.

The lessons taught by the war in the early handling and transport of patients who are seriously ill demand our very earnest attention. It was too often tragically brought home to workers in France how inattention to apparently trifling details was reflected in the whole subsequent course of a man's illness. For example, improper application of a bandage or inadequate fixation of a splint might result in the loss of a limb or even of a life. Medical officers as well as orderlies had to be trained in the application of specially suitable splints, and in all methods of resuscitation and preventive treatment which could reasonably be carried out in very advanced units. The prevention and curative treatment of shock and haemorrhage and of sepsis were the most important duties which faced the medical officer in these units quite apart from the problems of evacuation. The medical service at the front laboured under the disadvantage, when compared with civil service, in that the interests of the wounded man were subservient to the supply of ammunition, food, and reinforcements to the fighting line. Some of the work done by medical officers under these conditions was beyond all praise; for example, I know of many cases of severe gunshot fracture of the femur—a very deadly injury—which were so well attended to in advanced dressing stations during a big battle, when hundreds of severe cases were passing through such stations in a day, that the patients were passed along comfortably, free from delay and from any detriment, to hospitals in England, without having their original dressings and splints changed.

Lives are lost unnecessarily, even in our biggest towns, from the effects of shock and primary haemorrhage, and other ways, owing to the want of better organized help. I do not wish in any way to depreciate the efforts of

ambulance societies and such like, but I do think that early arrangements for the patient who is stricken down by a severe injury in the street or at his work suffer in comparison with those which were instituted at the front. For example, what factory has a special aid post where the patient can be specially warmed and otherwise cared for? Are splints specially suitable for transport available? Are special rooms set apart and specially equipped for the treatment of shock and haemorrhage even in the large hospitals of towns where severe accidents are common? Or again, in how many institutions is the routine of unclothing and cleansing a badly shocked patient omitted or modified until he has recovered from his shock? Many other questions in the same vein crowd upon us, and yet we know that, within easy range of shell-fire in France, everything really useful and practicable that human ingenuity could devise was done for similar patients! What was necessary for the wounded soldier is equally necessary for the injured civilian, whether the injury be due to accident or disease.

Again I must revert to the education of the student with regard to these practical matters. Take a question asked the other day as to what occurs in our own medical school, and I may say that the same holds good with regard to some other schools, and the larger the school the less chance is there of really remedying the defect unless the amount of clinical material is adequate. How many students before their graduation have, in their clinical work, actually passed a catheter, given an enema, passed a stomach pump, administered a hypodermic injection, "put up" a fractured limb, or even "made a bed," and so on, or even seen these things done? It is hard for patients to have to be submitted to unpractised although anxious efforts later on, especially when the graduate is not supervised. I remember in my student days how many of us went to the hospital nearly every evening during our service as dressers, and helped the house-surgeon in all sorts of ways. Evidently, so far as Aberdeen is concerned, this custom has practically gone out of fashion. It is to be regretted that clinical teachers there have not greater power over the students. There were comparatively few emergency cases then such as are common nowadays, but we learned a good deal from the treatment of those we did see. Emergencies are admitted most frequently in the afternoon or evening, and are operated on as soon after arrival as possible. Such operations are interesting and very instructive. I wish it could be successfully impressed upon students, and graduates also, that the clamant necessity for prompt treatment of an abdominal emergency cannot be appreciated unless they see for themselves the appalling state of the interior of the abdomen which results from delay.

A Sufficiency of Hospital Beds.

I can touch only very lightly upon a few of the other many lessons of the war. A very striking fact, when one considers it a little, is that a wounded or sick soldier was always provided for at once in hospital when hospital treatment was thought necessary. His name did not go on any waiting list, yet the large waiting lists of the hospitals of this country are regarded with comparative equanimity. The same attitude is apparent with regard to the permanent injury to health, and even to the loss of life, which occur in epidemics of serious illness owing to the fact that skilled nursing under suitable conditions is not available in adequate amount. Sir Napier Burnett has shown that lives were lost in number amounting to several divisions during the influenza epidemic of a couple of years ago. Yet in one instance, where cases complicated by pneumonia were housed in an extemporized building and nursed by volunteers, the death rate was greatly reduced. There should be no greater difficulty in rapidly adapting suitable public buildings in emergencies of that sort than there was in adapting them for hospital work during the war. The need for doing so is equally great when we consider the preventable mortality. Schemes should be drawn up for meeting the requirements of such emergencies.

In these days of inadequate hospital accommodation throughout the country, I wonder if sufficient consideration is given to the class of cases which are permitted to occupy the available beds. Perhaps I can best bring out what I mean by referring to the very important question which cropped up in France during periods of severe

fighting during which surgeons and others were taxed to the uttermost—a state of surgical stress that may be compared quite reasonably to the general great demand for available beds in civil hospitals. The matter I refer to is this: Human feelings, or even the surgical interest of a case, too often led surgeons to misplace their efforts by treating types of cases which required large expenditure of time, and which, after all, gave a low recovery rate. Thus, during a big “push,” it was difficult to persuade men to leave abdominal cases—in which under the best treatment, even in so-called “peace times,” the recovery rate rarely amounted to more than 50 per cent.—and to attend to other cases which, with timely operative intervention, recovered more rapidly and in far greater proportion, and of which two or three could be treated in the time taken up by one abdominal operation. If such promising cases were left over for a day or were sent down the line, by the time they were submitted to operation infection had gained such a hold that far more extensive measures had to be employed; in any case, a much longer convalescence was entailed, and in many cases even death resulted from the delay, and this even where the timely intervention would have resulted in the patients being fit for duty again in a comparatively short space of time. It was gradually being realized, however, that the exigencies of the military situation and the shortage of surgeons really demanded that the cases with the greatest prospect of recovery should receive preferential treatment, although consideration for the morale of the troops prevented this being carried out to any marked extent. The problem is really the same, when we come to think of it, in our civil practice. Manpower and conservation of time in relation to this ought to be considered more frequently. It is not good policy to sacrifice by delay in treatment any patient suffering from a disease or disability which can be rapidly cured, but which may develop to serious extent during the time of waiting for accommodation occupied by patients who are incurable, or who at best will never be able to display more than a low grade of efficiency. True it is, however, that some of these more hopeless cases must receive preference for admission to our educational institutions in order that our future medical men may be trained. One may be blamed for giving vent to inhuman opinions by those who do not care to face hard facts, but is it not the responsibility of the public to provide accommodation for all, and is it not our duty to bring this home to the public in every possible way?

The Best Sites for Hospitals.

Where should our large hospitals be situated? They represent the hospitals at the bases in France and in England. Only aid-posts, dressing stations, and so-called clearing stations were situated near the fighting line. The same arrangement could be made for civil combatants, as we have been calling the workers for the nation. Large hospitals need not occupy valuable space in their fighting area. These hospitals are much better situated in the green fields and woods on the outskirts of towns. Dressing stations and casualty clearing stations could be established in the busiest quarters of the town to perform functions similar to those they performed for the army.

Some Surgical Lessons.

The foregoing are some thoughts pertaining to general professional matters. Regarding more purely surgical subjects which I may be expected to discuss I do not intend to say much. You may hear and see in the wards of most hospitals from time to time the practical applications of many of the war lessons to surgical operations on civil patients.

The cruel effects of modern high explosives and the accompanying conditions of modern warfare forced the acceptance of many principles which were considered to be new. It is but just to say, however, that most of these principles had been advocated for several years before the war by certain surgeons. I shall mention only a few examples.

1. The treatment of infected wounds by excision of infected and devitalized tissue. This could sometimes be followed by suture of the wound, and in the hands of the best operators healing by first intention was obtained in the majority of cases which were amenable to such treatment. This, when compared with the general methods applied at the beginning of the war, was an incomparable

boon to the patient in all sorts of ways. It was not new. This method of treatment had been carried out in soiled wounds of soft parts as well as in compound fractures—for example, by Macewen of Glasgow, and, independently, by myself—for many years before the war; but unfortunately it was only tardily accepted as a routine procedure in the theatres of war. The application of the principle to the treatment of wounds of widely varying types in the different regions of the body met with such marked success that the saving of life, limb, and function was incalculable. The treatment, as I have indicated, is equally applicable to recently inflicted and even grossly infected civil wounds.

2. Perhaps the most theatrical of all general advances was in the treatment of severe wounds of the chest. At first practically all cases of severe thoracic wounds died—namely, those in which parts of the chest wall were blown away. So far as I could ascertain, these severe types formed about one-third of all wounds of the thorax in patients who reached the casualty clearing station alive. In a year and a half at Rouen base, the centre of many groups of hospitals, I did not see more than half a score of such cases. In one month at the front, during a battle, there were about 500 cases admitted to the casualty clearing stations of the army to which I belonged! In the last year of the war the best surgeons were operating on them so successfully that they were sending approximately 70 per cent. down the line, with every prospect that the patients would become useful citizens again. The war success in thoracic surgery has stimulated surgeons all over the world to cope with cases in a region which was previously left severely alone, save when comparatively simple measures could be applied. Yet before the war isolated surgeons in different parts of the world were striving to perfect technique along lines which the experience and stimulus of the war have shown to be correct. In no other field of surgery has development been so striking and so widespread. Experience in the war has at the same time shown that elaborate apparatus in the performance of such operations is not essential for success.

3. The effect of proper treatment of severe fractures was almost as striking as that in injuries of the chest. Severe compound fracture of the femur was, at the beginning of the war, one of the most fatal injuries in patients who survived long enough to come under the care of the medical service. The disastrous results were due to the effects of shock, haemorrhage, and sepsis. The late results in a large number of cases did not redound to the credit of the profession, yet by well-thought-out preventive work and extreme care in operative and after treatment gradually the mortality was enormously reduced and men were turned out again to civil life with marvellously useful limbs. In this class of case the institution of special hospitals with specially selected surgeons and equipment had much to do with the improvement.

In connexion with this class of injury, I must mention Thomas's knee splint. I do not suppose that Thomas in his wildest dreams ever thought that his splint would lead to the saving of literally thousands of lives in such a short period. This splint and its modification for use in fractures of the upper extremity are so valuable, especially during transport, that I recommend every one of you to become thoroughly conversant with the best methods of applying them. Thomas's leg splint and the similar arm splint should form part of the armamentarium of every general practitioner and surgeon.

4. The methods of combating shock and the effects of haemorrhage rise to one's mind in connexion with fracture of the femur. The description of such methods as were used at the front and which are so easily adapted for use by the general practitioner and hospital surgeon makes interesting and useful reading. We have to thank our Canadian and American *confrères* that the therapeutic value of infusion of blood or its substitutes became evident to the profession as never before, and this method of treatment is applicable to so many conditions in civil life that you should lose no opportunity of seeing it carried out.

5. The treatment of septic arthritis which was introduced during the war by Wilms, a Belgian surgeon, showed that time-honoured customs in surgical treatment, as in education, are not inviolate. Wilms demonstrated that the only way to drain a joint adequately is to provide free exit by means of ample incision, and then, by making the

patient move the joint spontaneously and vigorously, to cause the effusion to be forced out. Passive movements do harm. Under this treatment many even severely affected joints have recovered with free movement. To encourage movement of any sort while inflammation is still present in a joint, or indeed in any part, is contrary to all previous teaching, yet the recommendation is justified by results, as I have been able to prove to my satisfaction on several occasions during the war and since my return to civil practice. I wish to point out that the same factor as is involved in the use of active movements in joint sepsis is revealed at work in cases which recover after operation for peritonitis or pleuritis. In these, normal movements of bowel or lung speedily occur, and, mark you, it is better to dispense with drainage. If, in peritonitis, the bowel is so badly affected that peristalsis is paralysed, or if, after operation for pleurisy, the lung does not expand, recovery is, to say the least, a doubtful issue, even when drainage is established. In some cases of peritonitis, when the bowel is paralysed, temporary drainage of the bowel to remove its poisonous contents may have to be carried out in preference to other treatment, owing to the precarious state of the patient, or in bad cases of empyema all that may be possible is simple drainage of the pleural cavity. It seems to me, however, that in all these types of cases we are gradually being forced to rely more on the natural powers of the patient than on any artificial aids we can give. The rôle of the surgeon in such cases is merely to remove obstacles to natural processes of cure and then to clasp his itching fingers. My war experience has augmented the conclusion to which I had previously arrived, that, generally speaking, the use of drains must be included in the category of meddling surgery, or, in other words, that the necessity for the use of a drain is evidence of imperfect work. The trouble is that none of us can be sure of doing absolutely perfect work. Human limitations and mechanical weakness demand the occasional use of drains. For example, drainage of dead spaces which cannot be obliterated and drainage of a gall bladder to prevent distension of a sutured common duct may be necessary for safety. We must remember that, in the former instance, drainage is for removal of nutritive fluid only—that the presence of the foreign body, the drain, be it ever so soft, favours the growth of organisms. The less expert the operator, the greater the necessity for drainage.

One wonders whether drainage of septic joints, after removal of the cause of the sepsis or of the obstacle to healing, is really necessary any more than in a case of peritonitis. One wonders how long it will be before ordinary acute peripheral abscesses will be freely opened, wiped out, and immediately closed again by well-judged suturing. For years past I have been performing "delayed primary suture" in such abscesses.

As Wilms has shown, and as I had previously experienced during several years before the war, absolute fixation after so-called aseptic operations on joints is really a bar to rapid restoration of function. Is not Wilms's principle apparent in rational after-treatment of all sorts of cases? Should we not always encourage patients voluntarily to exercise normal functions as soon as possible, instead of interfering with natural processes by coddling them too long in bed, by using massage or electrical stimulation and other artificial so-called helps, when really the patient can better help himself?

6 and 7. Two instances of development of work at home deserve, I think, special mention. One was the enormous strides made by many surgeons in orthopaedic surgery in its various branches—bone-grafting, nerve-suture, and so on—and in appreciation of other than purely operative measures in orthopaedic treatment. This was largely due to the strenuous work of Sir Robert Jones, with whom I had the honour of being intimately associated for a considerable time. Another instance was the organization of the treatment of amputation stumps. Some of you may know from bitter experience what a nuisance a stump may be in itself, and that an artificial limb must receive very skilled attention before it is really serviceable and comfortable. Special centres have been instituted in various parts of the country to provide such skill for numberless sufferers. Sir J. Lynn Thomas of Cardiff has estimated that before the war there were 40,000 persons in the country who had lost one or more limbs. Surely this surprising fact is enough to make us preserve

at least some of these centres where the skill acquired will be still available, and to which we may send civilian patients to be properly fitted with artificial limbs and to be trained in their use.

I have said enough. I am afraid that I have dealt with my subject in a somewhat crude and superficial manner, but I hope that the suggestions which I have expressed may stimulate you, who have to deal with future developments, to think seriously and broad-mindedly about these and kindred subjects and to take an active part in the solution of the problems which are entailed.

Observations

ON

SPLENIC ANAEMIA: BANTI'S DISEASE.

PART OF THE BRADSHAW LECTURE ON THE SURGERY OF THE SPLEEN.*

BY

SIR BERKELEY MOYNIHAN, K.C.M.G., C.B., M.S.

F.R.C.S.

SURGEON, LEEDS GENERAL INFIRMARY; PROFESSOR OF CLINICAL SURGERY, UNIVERSITY OF LEEDS.

"BANTI'S DISEASE" is the name given to the condition described in 1883, and again in 1894, by Guido Banti of Florence. In 1866 Gretzel described a clinical condition of anaemia associated with splenomegaly to which Griessinger applied the name "splenic anaemia." The case occurred in a child 10 months old who suffered from dysentery and severe anaemia with considerable enlargement of the spleen, and enlargement, less considerable, of the liver and lymphatic glands. Examination of the blood showed that the proportion of white to red cells was not increased; the condition was therefore not leukaemic. In 1871 Wood described a "splenic form" of pseudoleukaemia, and reported a case in which the spleen was greatly enlarged, and there was severe anaemia without leucocytosis. Banti, in his later description mentioned above, considered the disease as possessing clinically three stages, merging gradually into each other. These stages were:

1. One in which there was enlargement of the spleen and a secondary anaemia, the duration being three to twelve years.
2. One in which the liver gradually enlarged, and the amount of urine underwent progressive diminution; the duration was brief.
3. One in which the liver gradually shrank in size and ascites appeared, the symptoms being those of an ordinary atrophic cirrhosis; the duration of this stage was between one and two years.

The disease was invariably fatal, and death occurred either from haemorrhage or from autointoxication from cirrhosis.

Clinical History.

Splenic anaemia was defined by Osler as "an intoxication of unknown nature characterized by great chronicity, primary progressive enlargement of the spleen which cannot be correlated with any known cause, anaemia of a secondary type, with leucopenia, a marked tendency to haemorrhage—particularly from the stomach—and in many cases a terminal stage with cirrhosis of the liver and jaundice." The clinical features of the disease, then, are the following:

1. A very chronic course, in which the symptoms progressively and steadily increase in severity, without amendment, and without any hope of spontaneous recovery.
2. A slowly progressive enlargement of the spleen. This is the first of all evidences of disease; the bulk of the organ undergoes an increase, at first apparently slight, but later more rapid. The ratio of increase probably remains unaltered throughout. The enlargement may finally be very considerable, though it is rare for the spleen to become as large as in myeloid leukaemia, or in some cases of Hodgkin's disease, or in malaria, or in Gaucher's disease. The spleen is not altered except in bulk, so far as physical examination shows; the surface is smooth, the notches apparent; there is no tenderness, nor is a friction rub felt or heard. It is said that a "bruit de diable" has been heard (Sippy, Rolleston) "due to eddies produced by slight torsion of the dilated veins in the gastro-splenic omentum or of the splenic vein." Seeing that clinical recognition of splenic enlargement is not possible until the

* Delivered before the Royal College of Surgeons of England on December 6th, 1920. The lecture is published in full in the *British Journal of Surgery*, January, 1921.

spleen is at least double the normal size, it is more than probable that the inaugural and early symptoms of splenic anaemia are quite unrecognized.

3. *Changes in the blood* are of the type found in secondary anaemia. The red cells may drop to less than 2,000,000 per cubic millimetre; the average number is one half of the normal. The colour index is low. In a series of fifteen cases Osler found the number of red cells to be 3,425,000 per cubic millimetre and the haemoglobin 47 per cent. A recent haemorrhage will of course affect the count very considerably; though it has often been observed that recovery after a haemorrhage is rapid, and that within two or three weeks the blood count may so improve as almost to reach the normal. The white cells are never above the normal unless there has been a recent haemorrhage, or an inflammatory complication is developing. Leucopenia is the rule. In Osler's case the average count was 4,520.

4. *The tendency to haemorrhage* is remarkable. Haematemesis especially is seen, occasionally with copious melaena. Other forms of bleeding are also mentioned in recorded cases: epistaxis, purpura, and haematuria are the most commonly seen. The amount of blood lost, especially from the stomach, may be enormous. I have seen two cases in which the apparently pure blood vomited within a couple of hours measured over three pints. Osler records a case in which three quarts of blood were lost within thirty-six hours. Recurrence of the haemorrhage is frequent. A remarkable case is related by Hutchison and Ledingham of a woman who was admitted to the London Hospital on account of severe haematemesis no less than thirteen times within a period of fifteen years. The blood comes in such crises, it is believed, from oesophageal varices and dilated vasa brevia, both of which are found in a large proportion of the cases.

5. *Affection of the liver.* In the later stages of the disease the liver enlarges, and presents the clinical pictures of Laennec's cirrhosis. Ascites is present with the hepatic enlargement, or in some cases without it. This terminal condition, in which the liver is enlarged and dropsy is present, together with the earlier conditions described, is often spoken of as "Banti's disease"; but if this latter term is retained it is perhaps wiser to use it only as a synonym of "splenic anaemia."

6. *An unknown causation.* The discovery of a cause for the splenic condition removes the case from the category of splenic anaemia. As I have said, the term "splenic anaemia," as originally used, included a group of diseases characterized by certain clinical features common to them all. Upon this group incroachments have steadily been made, and may well continue to be made, as our knowledge of the etiology of special diseases becomes by degrees more accurate.

7. *Other phenomena of less importance* may briefly be enumerated. A general enlargement of lymph glands is not present. Until the latest stage there is no alteration of the nutritive function. Occasional attacks of heaviness in the epigastrium, flatulence, and indigestion are observed, which lead, when haemorrhage occurs, to a diagnosis of "gastric ulcer." Such dyspepsias are less frequently seen than might be supposed. Rarely there may be slight pigmentation of the skin. If jaundice is present, the case is not one of splenic anaemia.

Differential Diagnosis.

This, as a rule, is not difficult. The mistake I have most commonly seen is the making of a diagnosis of *gastric or duodenal ulcer*. I have now seen 5 cases in which a patient suffering from splenic anaemia was referred to me as an example of these diseases. The absence of a clear history of dyspepsia, the presence of an easily palpable spleen, and the blood changes, soon revealed the true condition. The contrary mistake may be made. Rolleston relates the following case:

"Some years ago a middle aged man was under my care in St. George's Hospital. He was very anemic, and with a history of recurrent haematemesis. There was a tumour which appeared to be an enlarged spleen, and the condition was regarded as splenic anaemia. The necropsy showed that the tumour was a large hydatid cyst in the left kidney, and that a chronic gastric ulcer was responsible for the repeated haematemesis."

In any doubtful case an x-ray examination would almost certainly clear away the uncertainty and demonstrate the presence of a chronic gastric ulcer.

Cirrhosis of the liver has occasionally presented difficulties in diagnosis. The number of cases in which the splenic enlargement is considerable, and the hepatic enlargement slight must be excessively small. That the spleen may be much enlarged in cases of Laennec's cirrhosis is certain; and in such a condition a copious haematemesis might well raise a doubt as to the true diagnosis. Nansen and others consider that splenic anaemia is merely a type of hepatic cirrhosis in which the liver changes are relatively slight, at least until the final stages are approached. If a patient is first seen when the spleen is greatly enlarged, the liver cirrhotic, ascites abundant, haemorrhages recurrent, and all health and emaciation advanced, it is not certainly possible to say whether the case is one of advanced Laennec's cirrhosis or is in the terminal stages of Banti's disease. The accurate diagnosis is, however, made with little difficulty if the earlier stages of the disease are carefully sought.

Cirrhosis of the spleen and liver may be associated with a moderate degree of anaemia. In such cases the

symptoms of splenic anaemia are reproduced with remarkable accuracy. The differential diagnosis is achieved by a close study of the history, by a discovery of a positive Wassermann reaction, and by a recognition of the effects of antisyphilitic treatment. The latter, however, is not always successful. W. J. Mayo records five cases in which he removed enlarged spleens in conditions of chronic intractable syphilis with severe anaemia, when the patient had been resistant to careful treatment for syphilis, carried out during a period of several months. After removal of the spleen the anaemia rapidly disappeared and the syphilis was cured with comparatively mild antineutrophilic treatment such as had previously failed to affect either the syphilitic condition or the spleen. Conpland records a case in which the spleen was removed for "splenic anaemia" with much benefit; the patient died two years later, and syphilitic disease of the liver was found.

Pathogenesis of Banti's Disease.

The fact of utmost significance in connexion with the causation of this disease is that it is cured or arrested by removal of the spleen. This fact may be accounted for either by assuming that the disease is primarily and essentially located in the spleen, or by assigning to the organ the rôle of modifying the action of some agent situated elsewhere in the body. If the disease is primarily splenic, a search for a specific microbic infecting agent should ultimately be successful. Hitherto no convincing evidence of this has been found, although Hollins has argued strongly in favour of incriminating the colon bacillus. There is scope for further research in this direction; and the organ removed during life, if straightway examined, should provide profitable material for routine bacteriological investigation.

The enlargement of the spleen has been attributed to excessive haemolytic activity by those who consider the disease to begin in some other part of the body. But such a view does not sufficiently explain the fibrosis which is the outstanding histological feature of the disease. A chronic infective process would account for the enlargement as well as the fibrosis, and accord better with the absence of undue haemolysis of the red blood cells. In splenic anaemia the red cells never show "fragility." If there is a change the corpuscles may show increased rather than diminished resistance.

The anaemia, in like manner, may be regarded as an incident or as an essential part of the disease. Rolleston, a very distinguished authority, does not regard the anaemia as primary; he believes it to be secondary to attacks of very severe haemorrhage, chiefly because he finds that regeneration of blood takes place after these events. This view, however, is, I think, subject to the criticism that such severe haemorrhage is not invariable, and that the substance elaborated in the spleen need not be capable of affecting the bone marrow until after it has left the liver, where it has undergone modification. Further, whatever the poisonous substance may be, it need not completely arrest blood-cell development. A parallel case is, I think, sometimes furnished by subjects of leukaemia in which an intercurrent infection supervenes, with a temporary restoration of the normal blood picture.

Hollins regards the disease as being due to an active "intoxication" produced by the colon bacillus, whose "collysm" brings about the anaemia, whilst its actual presence in both spleen and liver accounts for the fibrosis of each organ. This view would put every kind of cirrhosis of the liver on the same level, because "collysm" could not be expected to vary radically in their action. The facts would be better met were it suggested that the spleen harbours various organisms, some of which only excite a local fibrosis, others induce a simple cirrhosis of the liver, and still others produce that form of cirrhosis associated with Banti's disease, with a toxic anaemia, and other specific symptoms.

In respect of the haemorrhage which is so conspicuous and alarming a feature of some cases, Rolleston considers that the enormously distended vasa brevia rupture into the stomach as a result of the torsion of the splenic vein caused by the great bulk of the organ. This opinion is certainly correct in many cases. The haemorrhage is so profuse, and so swiftly escapes from the stomach, that large vessels must be implicated. Such vessels as Rolleston describes are often seen in operations upon cases of splenic anaemia when abundant haematemesis has occurred. But this cannot, I think, be the whole explanation. The relationship between enlargement of the spleen and gastric haemorrhage is cryptic, but certain; for, as Balfour was the first to show, removal of the spleen may cure a patient

whose life has been jeopardized by severe and recurrent haemorrhages from the stomach. It is known to be toxic in origin in certain cases in which there is a lesion in the appendix, intestine, or gall bladder; and those also in which the lesion lies in the spleen or liver, or both.

Treatment.

The only treatment for splenic anaemia is splenectomy. The appropriate moment for the removal of the organ is chosen. It is inadvisable to operate soon after a grave haemorrhage, or when the spleen is extremely large. In the latter case, the effect of radium on the tumour should be tried; almost certainly it will cause a rapid and considerable shrinkage in the organ. If this should happily be the case, splenectomy is done when the spleen is at its smallest, and before it has begun to enlarge afresh, as it will certainly do after a few weeks. It is imperative to operate upon cases of this disease as early as possible. No other form of treatment needs consideration; the dangers and difficulties of the operation increase with the lapse of time; early operation means a more certain chance of recovery and a quicker convalescence. In the later stages the mortality of operation is higher, amounting to 25 per cent., as compared with an average of about 10 per cent. In the terminal stages operation becomes so dangerous that only the inevitably fatal outcome of the unhealed disease justifies its performance.

The degree of improvement that may take place is astonishing, even in the late stages of the disease, with advanced involvement of the liver. It is, as W. J. Mayo says, an evidence that the great power of the liver to regenerate its specific cells is utilized to the full.

The difficulties of the operation are greater in splenic anaemia than in any other disease. In almost all cases adhesions binding the organ especially to the under surface of the diaphragm are present. They may be numerous and exceedingly dense, and their separation may cause a copious and grave haemorrhage. But they are never so dense nor so strong as to prevent the completion of the operation. The details of the operation in other respects are the same here as elsewhere. At the Mayo clinic up to September 20th, 1920, 73 operations had been performed, with 9 deaths, equal to 12.3 per cent. The after-results are excellent; the rather high operative mortality is due to the technical difficulties of the late cases, which, apart from operation, would all be fatal.

ON THE END-RESULTS OF COLECTOMIES FOR INTESTINAL STASIS.*

BY

A. W. SHEEN, C.B.E., M.S., F.R.C.S.,

VISITING SURGEON, ORPINGTON AND SHEPHERD'S BUSH HOSPITALS,
MINISTRY OF PENSIONS; CONSULTING SURGEON,
KING EDWARD VII'S HOSPITAL, CARDIFF.

I propose to give here the results of complete colectomies performed in the years 1913-14. The war necessitated for me, as for many of us, a beneficial patience, in that "cures" were not too easily claimed by too immediate publication, and the term "end-results," tautological, but well understood, will be, I think, here justified.

The cases are only four in number, and one of them died soon after the operation. No excuse is necessary for bringing to notice such a small number, for it is of the small numbers, even of the solitary cases, that the profession desires, and ought to know. If the very wide usefulness claimed for this operation is justified, it ought to be very widely practised; the reasons for its necessity, its results, immediate and remote, and its mortality cannot be too well known.

I had long been interested in the work of Sir Arbuthnot Lane, and having, through his kindness, seen several of his cases and both watched and assisted at the operation of colectomy, I operated on these cases, which were selected as being advanced in type. The details and immediate results are recorded in the BRITISH MEDICAL JOURNAL of 1914, and these I will not now repeat. The "end-results" of the three cases are as follows:

CASE I.

W. C., male, aged 30 at time of operation on November 6th, 1913. I saw him on March 3rd, 1920, six years and three months after the operation. Back at full work as a bricklayer; feels a different man to what he felt before the operation; is no fatter. Quite all right until six months ago, since when he has had occasional abdominal pain, sickness, and diarrhoea. He is a healthy-looking man, with none of the stigmata of stasis. There is a large divarication of the recti, for which he wears a useless flannel binder. I wrote to his doctor, recommending a truss belt and attention to the teeth. I heard from the patient on August 5th that he felt very much better now than he had the new belt, that his teeth had been extracted, and he hoped to have the new set shortly.

CASE II.

A. M. S., female, married, two children, aged 34 at time of operation on March 2nd, 1914. I saw her on April 20th, 1920, six years and two months after the operation. She has got much fatter since the operation, takes food all right, and feels a different woman. Her friends have noticed that she has "cleared wonderfully." She has had two more children since, one now aged 4 and the other 2 years. All right until a few months ago, when she began to have lower abdominal pain and was constipated, her bowels sometimes not acting for a week. Her menstrual history was that her periods had always been profuse and frequent, that from January 14th to March 13th, 1920, there was no period, and she thought she was pregnant; on the latter date she had "flooding," and then a period on April 5th. She is a well-nourished, healthy-looking woman. The abdominal wound is soundly healed and she wears no support. The lower abdominal swelling and tenderness I found on vaginal examination to be associated with an enlarged uterus. I sent her on the same day to Dr. Ewen Maclean, who kindly saw her at once and pronounced her three and a half months pregnant, the fundus of the uterus being inclined backwards and to the right, possibly from—considered—the symptoms and physical—that miscarriage was not inevitable; also that parietal adhesions were not incompatible with the birth of two children subsequent to the operation. I heard from her on August 6th that the pregnancy was progressing naturally, and recently her doctor, Dr. McMichael of Vowchurch, Hereford, has written to me to say that she was confined on September 29th last and is going on well.

CASE III.

C. W., female, married, five children, aged 44 at the time of operation on April 30th, 1914. I was not able to see her myself, but Dr. T. E. Lloyd of Abergavenny kindly wrote as follows under date March 7th, 1920, five years and ten months after the operation: "Mrs. W. showed me your letter and I promised to write to you on her behalf. She is quite a different person, stout and well, with the exception of occasional attacks of diarrhoea, which I believe are neurotic. She used to be more or less constantly on one's list, but I hardly ever see her professionally now." I can supplement this from my note when I saw her five months after the operation, which says that she had then put on a stone in weight, her friends say she looks quite different, she is better than she has been for years, fat, healthy-looking, with a clear complexion; strong abdominal scar. She herself wrote on August 14th, 1920, saying that previous to the operation she had been under medical treatment for years, that since she has had excellent health and feels quite a new woman, that her people think she is a miracle and that she has got stout, her present weight being nearly 11 st.

What, then, are the end-results in these three cases? In all great improvement, which in the last two might be termed complete success. The qualifying details are: In the first case a ventral hernia with dyspeptic symptoms; in the second, adhesions, fortunately not interfering with pregnancy; in the third, diarrhoea occasionally. It is also to be remembered that a fourth case died after the operation.

There is an operative parietal infection in these and similar cases, which is, I think, too lightly regarded, being not referred to or just mentioned in the recording of operation results. As the aseptic precautions taken by operators are modern, minute, and successful under other circumstances, it is justifiable to regard this infection as coming from within. Gross infection from cut bowel ends should be avoidable, and the only explanations which suggest themselves are either that in toxic people there are micro-organisms in the peritoneal cavity which it can put up with, but the parietes cannot; or, that micro-organisms in the depths of the parietes are stirred into activity by the injury inflicted. Possibly the poorly vitalized parietes cannot deal with the few external micro-organisms which probably always remain in the skin and in its ducts, but this I regard as unlikely. The usual germ in the infection is *B. coli*. It may be that cultivations have been taken from peritoneal cavity or from cut parietes at the commencement of an operation: I do not know that this has been done, but it would be useful. That parietal infection is a

* A paper read to the Cardiff Medical Society, November 9th, 1920.

very real and not infrequent complication, I have not a doubt. It gives the surgeon a troublesome and anxious time after operations. That it has troubled Sir Arbuthnot Lane I recognize by his dressing of sterilized hot boracic fomentations, changed hourly after operation. I read of other operators having the same trouble, for instance, Mr. Waugh in his colopexies for stasis, to which operation I shall refer later. A ventral hernia, as in my first case, is not a satisfactory thing. It causes discomfort, dyspepsia, and inability to carry out fully the normal occupations. It requires a truss belt or a secondary operation with possibly the introduction of a filigree; this cannot be regarded as a satisfactory "end-result."

Internal adhesions may come from peritoneal disturbance, bringing into activity latent infection, or as a spread from parietal infection. Pain, flatulence, constipation, or diarrhoea may result from them; they are obviously undesirable, and are exemplified as possibly, but not actually, affecting pregnancy in my second case. The occasional diarrhoea of my third case Dr. Lloyd charitably regards as neurotic, but I assume it to be due simply to the removal of the colon.

There remains the fact of the death in my fourth case. As a necropsy was not allowed I can only testify to a hasty investigation through the operation wound, showing thin odourless pus in the pelvis and lower abdomen, nothing else. The strength and general condition of this patient (a female), the technique, the operation environment, and the after-treatment were similar to those in the cases which recovered.

There are ways which have been and are being evolved for preventing infection and adhesions. These I need not detail; but, whatever is done, the fact will always remain that the risks of those undesirable sequelae will always be greater in this class of case than in other classes of abdominal operations, the risk being greater the greater the "germ-soaked" condition of the patient. Their importance and frequency in preventing complete success can only be estimated by a careful consideration of all "end-results."

In spite of the good results in these three cases I confess that I am not enamoured of this operation. I cannot enter into the immediate dangers which exist, but the operation is undoubtedly a serious one. Is there anything which can take its place? I accept the toxæmia, its signs and symptoms, and that it is due to a blocking of the "ileal effluent" owing to displacements, kinks and adhesions of caecum and colon, these again resulting from upright posture, habitual constipation, and, I would add, tight clothing in women. The germ invasion with the absorption takes place in the ileum; the colon is the mechanical factor. Symptoms vary in degree and severity according to the amount of the delay and the intensity of the infection, the latter sometimes, but not always, depending upon the former. The surgical "purists," if I may call them so, say that there are only two lines of treatment, paraffin and a truss belt for the *slighter cases* and those which, for one reason or another, are not operated on; colectomy for the rest.

We are all acquainted with the long list of maladies which it is suggested by Lane may have their origin in stasis. A degree of absorption with its resulting ill effects may be conceived as the unhappy possession of most of us. It may be that a sterile ileum, if ever obtained, will help to confer immortality! The trained and, let us hope, unprejudiced eye of the advanced advocate of the toxic doctrine will diagnose many cases even among children, as "toxic," and will advise, at the least, belt and paraffin for those who have compassed 50 years or more of life's span.

Is there nothing besides the belt and paraffin but complete colectomy? Colectomy has been before the profession for many years, and has been most ably advocated, yet I am convinced that it is not a popular operation amongst surgeons. Go to any of our large hospitals and find out how many complete colectomies for stasis are done in a year. I think that there are very few. The operation is serious, and I question whether it will become less so, at all events in the hands of the general body of the surgical profession, by whom, if its wide applicability is accepted, it should be largely practised. The mortality is not easy to ascertain. Many cases recover and are greatly benefited; some cases die. But there is a third class in which there is

neither death nor recovery, but an almost hopeless discomfort nearly as bad as that which existed before the operation. Clark² records the "final results" in twelve cases; in six of these it was not satisfactory.

Are there other alternatives? Ileo-colostomy has proved surgically unsatisfactory because of the dead "bag" of colon left. I do not venture to discuss the medical treatment except to remind you of aperients. Nowadays, the cynic says, men look not for light and leading but for laxatives. In the lowest grade of treatment, the patent pill or potion, it is aloes, aloes all the way. Pick up a weekly newspaper in some country district and you will see among the advertisements therein the photograph of a female who beneath it describes, in simple but graphic language, all the symptoms of stasis, and all completely removed by so many boxes of somebody's pills.

Abdominal operations of various kinds are done and toxæmia previously present disappears. We shall be told of all such operations that they have produced their good results by freeing of the ileal effluent, that—for example—merit unexpected has been acquired by the removal of a "controlling appendix." Granted, but is not the lesson to pursue where possible a less dangerous and less drastic method than complete colectomy?

It may apparently not even be necessary to open the abdomen. I quote³ the following as to the operation of nephropexy: "I have visited these patients and observed the wonderful change in their appearance after a few days. The complexion becomes clearer and pigmentation around the eyes almost disappears and their friends are astonished at the improvement. . . . I have asked the patients to see me from time to time till they have completely recovered. One cannot get over facts. It is not a question of half a dozen cases but of hundreds."

A recent paper by Mr. G. E. Waugh,⁴ with which I am much more in sympathy, attributes the impairment of mechanical efficiency of the bowel with the resulting manifold evidences of tissue degeneration similar to those for which colectomy is advocated to an ascending colon which has retained and perhaps elongated its primitive mesentery; this developmental survival is present in 20 per cent. of individuals born. The symptoms manifest themselves in early adult life, and the drag affects not only the colon but also the right kidney, the stomach, the duodenum, and the gall bladder. An easy, safe operation—fixation of the ascending colon—cures, and symptoms of stasis disappear. Doubtless, again, especially as the appendix is removed, a freeing of the ileal effluent; but, if Mr. Waugh's contentions are correct, what a much safer way of freeing it than by colectomy! I am attracted by this operation and have carried it out recently in several cases, in all of which there has been immediate improvement.

It must be a commonplace with those, like myself, who have had a surgical experience of the abdomen extending over many years that various operative measures have seemed to cure patients clinically who, *inter alia*, had signs and symptoms of toxic stasis. As long ago as 1909 I read a paper to the Newport Medical Society⁵ on the treatment of abdominal displacements, and from my then experience I concluded that every case should be treated on its merits. From this conclusion I see no reason to depart. I can recall cases of operations on gall bladder, stomach, and appendix; of fixation of liver, of stomach, of colon; of the freeing of adhesions in various quarters; of other operations. In all there was more or less evidence of stasis, yet in all alleviation or cure resulted. I may relate a recent case as an example:

A young lady, aged 23, had moderate toxæmia, pain, that constipation with spurious diarrhoea which is so common, a dropped transverse colon as shown by a bismuth meal, debility, and loss of flesh. A scar with pain and tenderness represented a mysterious operation said to have been for intussusception when she was 6 years old, when tuberculous disease was found and the abdomen closed hurriedly. I operated, and a long incision revealed adhesions of large and small intestines to one another, and to the old parietal scar; adhesions between intestine and the left uterine appendages; a moderately dropped transverse colon and a diseased appendix; nothing else; no tubercle. The adhesions were divided, the appendix removed, and the transverse colon slung high up transversely to the abdominal wall. I have seen this lady quite recently, and she is wonderfully well, putting on weight, strong and active, bowels acting regularly without aperients. Since operation she has worn a truss belt. It is too early yet (five months) to give the end-result, but so far it seems to be "a cure."

Cases such as this may be taken to justify my contention that there are more surgical ways than one of curing toxic stasis, and that every case should be treated in accordance with the special indications it presents.

Neither, although I have been speaking as a surgeon, am I advocating surgery as the only remedy. Diet, drugs, aperients, paraffin, massage, exercises, posture, abdominal support, life, change of climate, spa treatment, all have their place in the treatment of intestinal stasis. In treatment, operative and non-operative, the psychic factor must not be overlooked. The rest and careful after-treatment is of benefit after all abdominal operations. The prevention of stasis and toxic foci should begin in babyhood and continue. The earlier the treatment the better, and then the less severe and the more effective it is. Prevention is indeed our final goal. Man steers his life's perilous course through the physical evils which beset him, and our hope for the future is that for the prevention of these evils we shall all work and strive so that stasis and its manifold ill effects may from being a problem of the present become a memory of the past.

A CASE OF DIBOTHRIOCEPHALUS LATUS INFECTION.

BY

GEORGE C. LOW, M.A., M.D., C.M., M.R.C.P.,
SENIOR PHYSICIAN, HOSPITAL FOR TROPICAL DISEASES, ENDSLEIGH
GARDENS, AND SEAMEN'S HOSPITAL, ROYAL ALBERT DOCK;
LECTURER AND CONSULTING PATHOLOGIST TO THE
LONDON SCHOOL OF TROPICAL MEDICINE;

AND

ELIZABETH J. O'DRISCOLL, M.B., D.P.H., D.T.M.,
HOUSE-PHYSICIAN, HOSPITAL FOR TROPICAL DISEASES,
ENDSLEIGH GARDENS, N.W.

CASES of infection with the broad tapeworm (*Dibothriocephalus latus*) are rarely seen in England. The infection is common in the Baltic provinces of Russia, in Finland, Sweden, Denmark, and Switzerland, and the presence of the parasite in many cases produces a severe form of anaemia, in some ways resembling pernicious anaemia. This is supposed to be produced by the excretion of a toxin. The tapeworm is contracted by eating raw fish in which the plerocercoid stage of the parasite is found.

The following case is interesting for two reasons—first, because there was no anaemia; and secondly, because of the successful expulsion of the worm by treatment. The patient, a Finn, evidently acquired the infection in his native country. He came to England in the course of his vocation, a seaman, and was admitted to the Seamen's Hospital, Greenwich, complaining of pains in the abdomen of an obscure nature. In addition there was a history of his having passed some segments of a worm in his stools. He was transferred to the Hospital for Tropical Diseases, Endsleigh Gardens, for observation and treatment.

H. K., a seaman, aged 18, born in Finland, was admitted to hospital with a complaint of abdominal pains. As the patient could not speak English, little history was obtainable from him. *Examination*.—Healthy looking boy, no sign of anaemia present; well nourished, no emaciation. Cheeks a good colour; conjunctiva, no anaemia; teeth good. Systems: Heart and lungs perfectly normal, no sign of any disease. Abdomen, nothing palpable, no pain on deep pressure. Liver and spleen not enlarged. Urine: No albumin, blood, or sugar. Faeces: Many ova of *Dibothriocephalus latus* present; no segments passed while under observation.

Blood count:	5,100,000
Red corpuscles...	8,600
White corpuscles...	90 per cent.
Haemoglobin...
Differential count:	55 per cent.

Treatment.

After being kept under observation for some time, during which he appeared normal in every way, eating and sleeping well, the following treatment was adopted.

After a very thorough starvation for two days, and a saline purge on the evening of the second day, liquid extract of filix mas was administered on the third morning as follows: A capsule of 20 minims at 8 a.m., a second of the same dose at 8.30 a.m., and a third at 9 a.m.—that is, 60 minims in all. A saline purge (magnesium sulphate) was administered at 12 noon. Apart from a slight tendency to sickness there was no trouble with the drug. At 4.30 p.m. the whole worm was passed, including the head. There was no sign of any second worm, this being confirmed by the disappearance of ova in the stools on subsequent days.

It is quite possible that the patient had only had the worm for a short time, and if this were so, it might account for the absence of anaemia. The worm, on the other hand, was a very large one and fully developed in every way. Another interesting feature in the blood examination was the absence of eosinophilia. The question of blood destruction, in helminthic infections generally, is a very interesting one, and more work might profitably be done upon it. The ordinary tapeworms, *T. saginata* and *T. solium*, do not appear to upset the blood picture in any way, and even with the *D. latus* a personal susceptibility may be required before the severe types of anaemia described appear. The lad was discharged from the hospital cured.

THE ECONOMIC ASPECT IN EYE INJURIES:

A PLEA FOR EARLY TREATMENT.*

BY

T. LISTER LLEWELLYN, M.D.

This paper is based on an analysis of the total accident claims made on the North Staffordshire coal and iron owners during the past two years. Cases in which incapacity lasted less than four weeks have not been included, nor have several cases of injury to the eye followed by the onset of miner's nystagmus, either immediately or within four weeks. Cases arising in previous years and settled during this period have also not been included.

TABLE I.

	Total.	Mines.	Iron and Steel.
No. of workmen...	45,000	35,000	10,000
No. of admitted claims (all accidents)	3,283	2,761	522
No. of cases of injury to the eye...	163*	126	37
Total cost...	£8,286		

* This figure (5 per cent.) agrees closely with those given by Collis in his paper on "Eye Diseases caused by Occupation," *Ophthalmoscope*, vol. xiii, p. 492.

The 163 cases may be divided into four groups:

1. Cases returning to work.
2. Cases of serious injury necessitating immediate expert treatment at the infirmary.
3. Cases in which a comparatively trivial injury is followed by nystagmus.
4. Cases in which a slight injury, either through neglect by the patient or lack of expert treatment, is followed by serious and permanent injury to the eye. Five of these cases developed a severe attack of nystagmus.

Even in the first group lack of proper treatment delays the return to work:

F. W. Blow in eye January 3rd. On January 16th there were still two pieces of coal embedded in the cornea. Played six weeks.

J. B. Blow in eye June 3rd. Foreign body in cornea on June 18th. Played five weeks.

J. H. Struck by iron stone January 31st. On February 4th there was marked injection of eye with a foreign body in the cornea. Played five weeks.

* Read before the Staffordshire Branch of the British Medical Association on November 25th, 1920.

These cases were sent on to the infirmary for treatment. It is probable that if the foreign bodies had been removed at the time of the accident there would have been little loss of time.

In the second group the original injury has either damaged the eye beyond recall or the patient is receiving the best treatment available. In the third group it is possible that early treatment might prevent the onset of the disease, as symptoms are often delayed. It is important to remember that there is a history of accident to the eye in 10 per cent. of all cases of nystagmus.¹

I wish chiefly to emphasize the importance of the fourth group. In these cases neglect by the patient, lack of proper directions, failure by the medical attendant to remove a foreign body or appreciate the presence of infection, may lead to results which can only be described as disastrous. On many occasions I have seen foreign bodies left in the cornea seven to ten days and septic ulcers of the cornea with hypopyon treated with boric lotion. I have often sent such cases, presenting themselves for examination under the Workmen's Compensation Act, for immediate expert treatment to the local institutions.

D. B. Foreign body in cornea one month after accident. Played seven weeks.

C. B. Struck with wire May 18th; seen May 31st. Marked injection of eye, corneal wound; shallow anterior chamber, opacity of lens. Treated with boric lotion. Sent to infirmary; admitted and iridectomy performed. Still playing five months afterwards.

J. D. Struck by coal. Attended infirmary seven days after accident. Septic ulcer leading to rupture of globe. Eye removed. Nystagmus developed afterwards.

J. L. Struck by coal June 28th. Septic ulcer and iris developed before treatment at infirmary. Eye removed August 20th to prevent sympathetic ophthalmia. Vision in remaining eye.

J. B. Struck by coal May 18th. On May 31st septic corneal wound with iris. Treated with boric lotion. Sent to infirmary and admitted at once.

A. K. Septic ulcer of cornea with complete loss of sight from scar formation.

J. G. Extensive corneal opacity after septic ulcer. Nystagmus developed.

L. D. Corneal wound March 31st. Returned to work July 5th. Failed after five turns from onset of nystagmus. No symptoms before accident.

C. M. Blow in eye March 25th. Septic ulcer developed. Admitted to infirmary April 30th. Eye removed May 3rd. Well marked nystagmus September 3rd.

TABLE II.—Nature of Injury (163 Cases)

Burns of conjunctiva, injuries of eyelids	11
Contusions of globe	2
Conjunctivitis due to dust and injury	7
Injury to cornea:	
Slight	85
Severe	10
Septic ulcer	33
Penetrating wounds of eye	15

In 41 cases there was complete loss of sight in the affected eye.

Iris lost	17
Corneal opaque	17
Cataract	10

TABLE III.—Septic Ulcer of Cornea (23 Cases)

Complete loss of sight in affected eye	15
Iris lost	6
Severe attack of nystagmus followed in	5

The eyes were lost in 11 of the 15 cases of penetrating wound of the eye.

TABLE IV.—Disposition of Cases at end of Period in Review.

	No.	Total Cost	Duration of Incapacity in Weeks
Cases terminating naturally	79	£ 1,215	88
Cases terminated by commutation	19	£ 4,697	190
Cases unsettled	65	£ 2,773	357

In the 55 cases settled naturally or by commutation the period of incapacity was:

Between 4 and 6 weeks	40
Between 6 and 10 "	23
Between 10 and 12 "	15
Between 12 and 13 "	8
Over 13 weeks	7

TABLE V.—Unsettled Cases (65).

Receiving full compensation	35
Receiving half difference	11
Receiving no pay	19

PREVENTIVE MEASURES.

In occupations where there is special danger of injury to the eye goggles should be worn. Collis (quoted above) states: "Goggles have saved hundreds of eyes; thousands have been lost for want of them." Workmen should be warned of the danger of neglecting eye injuries, and should be encouraged to report at once at the first aid room. The first aid room should contain in addition to the usual outfit:

- One Winchester quart of boric lotion.
- One Winchester quart of sodium bicarbonate solution (gr. x to the ounce) for acid burns.
- Castor oil (two ounces).
- Camel hair brushes (two).
- Undine eye washer.

The cost of this outfit is 8s.

The following instructions to the first aid attendant should be posted up in each first aid room (poster foolscap size):

INJURIES TO THE EYE.

INSTRUCTIONS TO FIRST AID ROOM ATTENDANTS.

To Wash Out an Eye.

Use warm boric lotion and the eye washer.

To Remove a Foreign Body.

The foreign body may be under the lids or embedded in the eye.

If embedded in the eye
Do not attempt to remove it.

Wash out the eye.

Drop in some castor oil.

Cover the eye with a bandage.

If under lower lid

Pull down lid and wash out the eye. Use a camel hair brush if necessary.

If under upper lid

Push the lower lid under the upper lid, and ask patient first to close and then to open his eye. Repeat the process. If this is unsuccessful, evert the upper lid as follows:

Seat patient on a chair and stand behind him.

Lay a wooden match half an inch above the eyelashes.

Press the match backwards and pull the eyelashes over it.

The foreign body will then be seen, and may be removed by washing or the use of the camel hair brush.

After removal of the foreign body, drop in some castor oil and cover the eye.

Lime Burns

Remove particles with wool soaked in castor oil.

Wash out the eye. Drop in some castor oil.

Advise all men to see their Doctor at once.

A supply of printed slips giving directions to the workmen should be available. These slips should be handed to the workman when he reports his accident. The instructions should also be posted at the pit head or at the usual notice board in poster size. The slips are four by five and a half inches and the posters of foolscap size. The subject matter given below is the same in each case.

INSTRUCTIONS TO WORKMEN.

INJURIES TO THE EYE.

Report at first aid room and afterwards to your Doctor all injuries to the eye.

Do not try to remove any particle which cannot be easily washed away.

Do not rub the eye.

If eye is painful drop in some castor oil.

Cover eye with clean bandage.

LIME BURNS.—Go to first aid room. Wash out the eye and afterwards drop in some castor oil.

A neglected eye may lay blind to the doctor.

Go to your Doctor.

Under no circumstances should a solution of cocaine be part of the equipment of a first aid room as the feeling of comfort following the use of the drops will put off or delay the visit to the doctor.

TREATMENT.

I do not propose to enter into the question of treatment, but wish to confine myself to urging the necessity for the greatest care in all cases of injury to the cornea. The

treatment of eye injury belongs to a highly specialized branch of surgery, and should not be undertaken in a light-hearted manner by the general practitioner. If the doctor is in any doubt he should not hesitate to obtain expert advice. In his evidence before the Workmen's Compensation Committee Mr. Pooley (Q. 19,787) states that in Belgium special hospitals or wards, subsidized by the State, undertake the treatment of eye injuries for small fees. In this country the general opinion is against State interference, but both employee and employer have the right to demand adequate medical attendance.

SUMMARY.

What is the position of the workman and employer at the end of the period under review?

Workmen.—Forty-four men have lost the use of one eye and nineteen have developed nystagmus.

Settled for lump sum	19
Working full time	98
On half difference	11
Playing	35
Time lost at five turns a week=17,250 shifts.				

Employer:

Loss of output corresponding to time lost by workmen.
Expenditure in compensation, £8,286.
Liability of 68 unsettled cases.

It is the custom of employers to reserve a lump sum for unsettled cases. In the Yorkshire coal field one mutual indemnity society has reserved nearly three-quarters of a million pounds for all unsettled cases (Gillhespy, Q. 5731, Workmen's Compensation Committee). The money thus put by is not available for the purpose of expansion of work, and is a very considerable drain on small employers.

THE DROOPING SHOULDER SIGN OF
PHTHISIS.

BY

W. C. RIVERS, M.R.C.S., D.P.H.,

TUBERCULOSIS OFFICER, BARNSELY DISTRICT, WEST RIDING, YORKS.

Of the last 50 consumptive cases (to go no further back) sent me for diagnosis, in just half there has been present a physical sign not mentioned in any British textbook. On the affected side, or (generally) the side of more extensive or older disease, the point of the shoulder and the nipple are lower than on the other side; the nipple is also smaller and seems to lie further back. Behind, the scapula is lower—its inferior angle may reach 3 in. below that of its fellow—and is at a different distance from the spine, mostly nearer to it. Muscular atrophy also is noticeable, a little of the pectorals, but far more of the upper part of the trapezius. The superior border of that muscle, instead of running straight from neck to shoulder, is flattened, wasted, hollowed out, so that, as compared with the opposite side, much less of it shows above the clavicle when viewed from the front, and above the spine of the scapula when viewed from behind. The sign occurs indifferently in men and women, although more marked in the former; and as regards association with the type of phthisis, in this order of descending frequency—juvenile hilus cases, a rather large proportion; third stage cases (Turban-Gerhardt), very nearly half; first stage cases, nearly half; second stage cases, about a quarter. I have seen it develop in the course of a few weeks. Photographs may be seen in a book of mine.¹

The above is the sign in full force. Krönig² says that in early tuberculosis of one apex the scapula of that side may be further from the spine, and often lower, than its fellow; in respiration its movement may lag; while in males and nulliparous females the corresponding nipple has likewise a lower level. The textbooks of Schröder³ and of Bandler⁴ cite different authors who have noticed atrophy of the shoulder muscles on the affected side, while the latter mentions Aufrecht's observation, that on the side of disease the acromial end of the clavicle, mostly higher than the sternal one, may dip below it.

As to causation, the sign is pretty certainly tuberculous in origin; a somewhat similar asymmetry described

in lunatics is unaccompanied by muscular atrophy. The characteristic unilateral trapezius atrophy suggests that the weakening of this muscle in its upper part causes the corresponding half of the shoulder girdle to sag with the weight of the arm. The natural muscular inferiority of the left side has nothing to do with it, for the right trapezius is oftener affected than the left, agreeably with the fact that the right lung is more frequently tuberculous. I have seen a case, too, where the trapezius on the healthy side was much bigger, although scarred by a penetrating gunshot wound. Pottenger,⁵ like Fischer, describes spasm of the muscles overlying a tuberculous apex, ascribing it to reflex irritation reaching the muscle from the chronically inflamed lung by nervous paths (sympathetic to the cord and thence motor). The spasm goes on to pulpy degeneration. He does not mention atrophy, which seems to me far commoner than either spasm or pulpiness. Probably the spasm quickly goes on to atrophy. In bone and joint tuberculosis muscular spasm and atrophy are very common phenomena.

Lastly, the sign has great practical value. It is clear, objective, definite. It has commended itself to the general practitioners of my district, and to a Pensions Board. In children's phthisis, in chronic bronchitis complicated by a little patch of tubercle, it comes like a beacon.

MEDICAL, SURGICAL, OBSTETRICAL.

OPHTHALMOSCOPIC APPEARANCES IN CERTAIN
RARE CASES OF DIABETES.

The ophthalmoscopic appearances in diabetes mellitus do not usually present any characteristic changes; in a few cases diabetic retinitis is detected (7 per cent. in a consecutive series of my own cases); but in certain very rare instances, associated with a special blood condition, a striking change is seen. The retinal blood vessels, instead of having the normal deep red colour, all appear milky white or pinkish white, whilst the rest of the fundus has the normal red colour.

To the naked eye the blood in diabetes does not usually present any striking alteration in appearance, but in a few very rare cases the blood is light pink in appearance. It has the colour of blood-stained pus, and is thicker than normal blood, being in appearance somewhat similar to anchovy sauce, but with a brighter tint. In some of these cases the ophthalmoscopic changes in the retinal vessels just described have been detected. It has been stated that chemical examination has shown that the fat in the blood has been increased in these cases, and the condition has been described as "lipæmia."

I do not know by whom the ophthalmoscopic changes were first described. I read of them ten years ago, and a small number of cases are on record; but as the condition is not well known, the following brief note may be of interest to those who are devoting attention to ophthalmoscopic examinations in medicine:

A man, aged 22, was sent to me for consultation by Dr. H. Ramsden of Dobcross, on account of severe diabetes mellitus. Sugar had been detected in the urine six months previously. Thirst and diuresis had been prominent symptoms, and he had suffered from a carbuncle on the neck. In the routine examination of the blood I was surprised to find that it had not the ordinary deep red colour, but was light pink in colour and very thick. It had the appearance of blood-stained pus, or of anchovy sauce, but with a brighter tint. I examined the eyes with the ophthalmoscope and detected what I expected—the peculiar changes in the appearance of the retinal vessels of which I had read many years ago. All the retinal blood vessels and branches thereof were white; the retinal veins were cream white, the retinal arteries were cream white with a slight pinkish tinge. The optic discs were normal. The rest of the fundus had the normal red colour. Vision: R. 8; L. 2. This ophthalmoscopic appearance is probably characteristic of the blood condition just described.

I fixed an appointment for a further blood examination, but the patient was too ill to keep the appointment. It

was not therefore proved that the peculiar appearance of the blood in this case was due to "lipaemia." Moreover, the older methods of estimation of fat and allied substances in the blood have been criticized by modern physiological chemists. But the striking ophthalmoscopic changes and the marked alteration in the appearance of the blood were changes which could be recognized by the naked eye without other methods of examination. The ophthalmoscopic appearances just described are, therefore, those found in certain rare cases of severe diabetes, in which the blood has been very pale and thick, like blood stained pus; such blood condition in cases previously recorded having been attributed, rightly or wrongly, to lipaemia.

Manchester. R. T. WILLIAMSON, M.D., F.R.C.P.

SEVERE TETANUS SUCCESSFULLY TREATED BY LARGE DOSES OF ANTITETANIC SERUM.

THE case of tetanus which I report below is of interest because of the short incubation period, and because a cure was effected by the use of antitetanic serum, high doses of which were given without any apparent ill effect to the patient.

A boy, aged 9, fell and received an abrasion, about half an inch in diameter, of the skin of the right knee. This became septic, and four days later he complained of what appeared to be toothache, accompanied by stiffness of the jaws. On the seventh day after the accident the father, who had been a soldier, suspected tetanus and brought the child to hospital.

On admission he complained of pain in the back, stiffness of the jaws, and pain and difficulty on swallowing. Temperature 98°, pulse 120, respirations 30. He lay in bed on his back with rigid neck muscles, slight head retraction, and typical "risus sardonicus"; he could barely force the tip of his little finger between his teeth. Neither at this nor at any other time were there convulsions. On the evening of the third day there was slight arching of the back for a couple of hours. Sleeplessness and thirst were marked during the first four days. He showed no signs of improvement until forty eight hours after admission; during the subsequent six days all the signs and symptoms disappeared gradually with the exception of the sardonic appearance, which can still be slightly noticed. He was discharged from hospital, cured, on the twenty sixth day.

The following treatment was carried out: On admission the patient was given an anaesthetic and the wound was excised, a good margin of healthy tissue being removed all round. The cavity was washed out with hydrogen peroxide, left open, and dressed daily with tinct. iodi. Antitetanic serum was given intrathecally (after lumbar puncture), intramuscularly, and subcutaneously. The doses, expressed in units, were:

First day	intrathecal, 1,500	intramuscular, 10,500
Second day	" 3,000	" 12,000
Third day	" 3,000	" 13,000
Fourth day	" 3,000	" 15,000
Fifth, sixth, and seventh days	6,000 units intramuscularly	

Altogether 94,500 units were given. A rise of temperature was noted during the first four days regularly at 6 p.m., three hours after the injection of serum. On the first day it rose to 101°, on the second to 102°, and on the third and fourth days to 105°. There was no evidence of ill effect, and the boy looked quite well in spite of these high temperatures. To prevent bruising on convulsions, an anaesthetic was given for all injections except the subcutaneous. There was a marked serum rash, which cleared up soon after serum treatment was discontinued. In addition, a mixture of potassium bromide gr. viij and chloral hydrate gr. viij was given thrice daily. The bowels were kept freely open. The diet consisted at first of nourishing fluids given frequently and in small quantities; later a light diet was given, and eventually ordinary diet.

A previous case, that of a woman, aged 37, in whom the incubation period was seven days, received similar treatment, except that the total dose of serum amounted to 33,000 units in four days—6,000 units intrathecally and the rest intramuscularly. In this case there were severe generalized convulsions every quarter of an hour, and death occurred on the fourth day.

The Royal Post-mortem Hospital

T. V. CARFY, M.B.

THE report of the Gordon Memorial College at Khartoum has just been circulated. It contains an account of the varied activities of this well-known institution. The College has now recovered from the limitations imposed upon it by the war, the vacancies in its scientific staff have been filled, and with Major R. S. Archibald, D.S.O., M.D., in place of the late Dr. Chalmers, at the head of the Wellcome Tropical Research Laboratories, a continuation of the series of researches noted by Dr. Chalmers in the present report is to be expected.

Reports of Societies.

GASTRIC AND DUODENAL ULCERS.

At the meetings of the Royal Glasgow Medico Chirurgical Society held in the Faculty Hall on December 3rd and 17th, 1920, a discussion took place upon the "Treatment of gastric and duodenal ulcer." Professor RALPH STOCKMAN, representing the physician's point of view, pointed out that questions regarding treatment and subsequent results were by no means identical in gastric and in duodenal ulcers. Diagnosis was often very difficult and mistakes not infrequently occurred. Fortunately, in this discussion, diagnosis was not under consideration; they were dealing with accurately diagnosed gastric and duodenal ulcers. It was known that gastric ulcer was common in anaemic young women and that duodenal ulcer frequently occurred in men in the prime of life and apparently in perfect health otherwise, but the reasons were unknown. Other facts were known, such as age incidence and morbid anatomy, but regarding the basic cause of these ulcers we were still very much in the dark. It was not known whether they were primary lesions, or secondary lesions following upon other unrecognized deeper lying causes. The importance of this in reference to treatment was self-evident, and if cleared up it might explain much in our failure to treat many of these cases more successfully.

Professor Stockman thought that to obtain the clear view necessary for the immediate question of treatment and its results, it was necessary to consider the recent and the chronic ulcers apart. It was certain that many people had acute ulcers of stomach and duodenum without any definite symptoms, and that the ulcers healed of themselves and probably never gave rise to further trouble. But if pain, indigestion, haemorrhage, or other symptoms supervened, so that we were fairly sure that we had an ulcer to deal with, clinical experience had put in our hands fairly efficient methods to allay these symptoms and presumably to induce healing. Absolute rest in bed was a first essential, so was light, easily digested food. Attention to the bowels, and the administration of bismuth carbonate, magnesium carbonate, and possibly precipitated calcium carbonate, seemed in most cases to cause healing in from three to five weeks. A dietetic treatment based upon Lénhartz's was found to be, on the whole, successful. Treatment was generally stopped too soon, and it was most important to endeavour to make sure that the ulcer was soundly healed. It should be possible to prevent its becoming chronic, for nearly all the prolonged ill health of gastric and duodenal ulcers was due to the ulcers becoming chronic and refusing to heal. Regarding systematic drug treatment to produce sound healing, physicians had shown a great want of enterprise. A marked feature was that many patients who had had gastric and duodenal ulcers kept well for long periods, but relapsed under worry, business and domestic strain, and exposure to cold. Anaemia should be carefully attended to. It was the chronic ulcer which gave trouble in practice. Many of its victims were never free from indigestion, pain, and poor general health; they had constantly to diet themselves; they might have recurrent haemorrhages, and their working capacity was greatly lowered. Medical treatment had shown lack of enterprise and initiative, and the treatment outlined above seemed to be the best we could do. Surgery claimed much regarding operative interference. While operation for perforation, pyloric stenosis, deformities, obstruction by adhesions, invasion of the pancreas, liver and gall bladder, often showed brilliant results, this was by no means invariably so. Cases of severe haemorrhage sometimes came into this category, but not often. The performance of gastro-enterostomy for the cure of uncomplicated chronic or recurrent ulceration did not stand on anything like this secure basis, and possibly it should not be done at all for this purpose. Regarding the claims made for it, almost every test showed it wanting. The strict rest and diet after the operation did good, but recurrences and trouble occurred afterwards very much as in unoperated cases. Reurgitation of bile was a dreadful sequel to the operation. In the past year, when discussing gastric ulcer at the British Medical Association annual meeting, Moynihan

stated that he had abandoned gastro-enterostomy as a method of treatment, his choice now falling on gastrectomy. Mayo, on the same occasion, advised gastro-enterostomy and burning out of the ulcer. But why operate at all? It was said to lessen the risk of perforation, but perforation was a rare occurrence, it could not be foretold, and could be dealt with efficiently by operation if it did occur. Excision of the ulcer was another operation which had been tried without immediate success, and it was claimed that this prevented the after-development of cancer. Cancer did not, however, commonly develop in the duodenum. If ulceration *per se* were the preceding and determining cause, one would expect to find cancer equally common in the duodenum. The matter was very far from being settled at present.

Mr. JAMES H. NICOL, representing the surgeon's side, remarked upon the impossibility of separating "treatment" from "etiology" and "symptomatology." Further, gastric and duodenal ulcers were absolutely different in two particulars—gastric ulcer tended to become malignant, duodenal ulcer practically never did. Gastric ulcer was common in young females, duodenal affected middle-aged men. In his opinion pancreatitis and gastric and duodenal ulcers were steadily following appendicitis, intestinal obstruction and cholelithiasis in that their immediate treatment was surgical. Referring to diagnosis, Mr. Nicol spoke of the results of physical examination, chemical and physical examination by test meals, radiography, gastroscopy, and exploratory laparotomy, and, having examined each method critically, concluded that the last word in diagnosis lay with the surgeon. With regard to treatment, not a few surgeons, including himself, were being steadily driven to the position that for these affections operation was the safe course. For duodenal ulcer, enfolding with closure of the pylorus was the proper course. This necessarily involved gastro-enterostomy. For gastric ulcer, excision or enfolding constituted the treatment; such treatment might or might not involve the super-addition of gastro-enterostomy. The decision in regard to that would depend upon the site of the ulcer and the degree of distortion of the stomach produced by the excision or the enfolding of the gastric ulcer. In regard to some points of detail:

- (a) Large parietal incisions should be employed so that the other organs in the abdomen might be examined.
- (b) Gastric and duodenal ulcers apparently cured by medical means not infrequently relapsed, perforated, bled, or became malignant.
- (c) Microscopic examination of all excised gastric ulcers was advisable.
- (d) When gastro-enterostomy was called for alone or in addition to pyloric closure or excision of the ulcer, in most cases the ordinary posterior operation answered well. When this led to bile regurgitation the surgeon must fall back upon one of three methods: (1) Gastro-enterostomy plus entero-enterostomy; (2) Roux's gastro-enterostomy "en Y"; (3) a modification of that permitting of side-to-side union.

Dr. R. O. ADAMSON presented the case from the point of view of the general practitioner. Sooner or later the majority of cases yielded to medical treatment, and in course of time diet and other treatment was relaxed. Owing to the exigencies of practice many cases of beginning ulceration were treated without having been investigated with the complete thoroughness that it would be best they should have, so that probably many were cured because they were treated in their earliest stages. Not infrequently later events proved that ulcer had been present. So, further, if the presence of ulceration was definitely proved, and the treatment then was more careful and more prolonged on the familiar lines, cure would result in a number both of duodenal and gastric ulcers. In numbers of cases the cure, however, was only partial, in so far as the ulcer was not completely and soundly healed. The patients, once the symptoms had disappeared, returned to unhealthy surroundings, to food wrong in quantity and quality, to conditions which in one way or another led to the return of their trouble, with the old symptoms. The ulceration became more difficult to heal, and they merged by degrees into the large class of chronic and recurrent cases. What seemed to be required was a much prolonged after-treatment in the early cases, for the frequent recurrence was apt to be followed by those deformities of the stomach, the pylorus, and duodenum which might be worse than the primary disease. Dr.

Adamson then considered in more detail how the cases presented themselves to the practitioner. He believed that after-treatment should be continued not for weeks or months, but for years. The question of suitable diet was all-important.

Dr. JOHN COWAN said that the mortality was considerable, and in a series of 120 patients who were in his wards suffering from some form of ulceration of the stomach or duodenum 15 died—that is, 12.5 per cent.; 8 died from haemorrhage, 4 from perforation, 1 from toxæmia, 1 from exhaustion, and 1 from unascertained causes a few days after leaving hospital, refusing operation. He thought that syphilis was an occasional cause of ulcer in adult men. He had recommended operation in 21 patients (17.5 per cent.), and in 2 others operation had been required within a short period of their discharge from hospital. Operation had been performed in 17 cases—7 times on account of recurrent haemorrhage, 7 times on account of dilatation of the stomach, thrice for a perforation; two of these patients died, both from perforative peritonitis. The ulcer was situated in the duodenum in 10 cases and in the stomach in 6. In the other patient no ulceration could be discovered at the operation. In another patient, who died from haemorrhage, a small erosion proved the source of the bleeding. In treatment the best results were obtained by the close co-operation of physician and surgeon and careful examination by every possible means of the particular features of each individual group. In his series the mortality in the operation group was 11.7 per cent., and in the non-operation group 12.6 per cent.

Dr. SOUTTAR MCKENDRICK said that the frequent occurrence of severe haemorrhage in duodenal ulcer suggested the question whether operation was justified in all cases. In the operation of . . . the physiological mechanism received . . . action was disturbed and the nervous mechanism thrown out of gear. Undigested food was hurled into the small bowel where the intestinal juices were incapable of digesting it, with the consequence of flatulence, eructations, and possibly diarrhoea. Should operation not be limited to gastric and duodenal ulcers with severe recurrent haemorrhages, pyloric stenosis, gastric tetany or perforation, or where there was evidence of a localized peritonitis or subphrenic abscess? The x rays would be a reliable guide when the results obtained were carefully interpreted. When the stomach emptied in five or six hours, prolonged medical treatment should be applied to patients resting in bed. If pyloric stenosis followed, operation could be resorted to. Occult blood in the faeces was not a sufficient reason for operation.

Sir KENNEDY DALZIEL agreed that a large proportion of gastric ulcers required operation. He had been much troubled with one type of gastric ulcer—on the lesser curvature, when there was no hing at the pylorus or in the rest of the stomach. Although a great deal of treatment was tried, the patient's life was one of torture and discomfort. Acute ulcers did not call for operative treatment except after treatment had first been tried. In America the feeling was that gastrectomy was the right operation. How many physicians or pathologists had seen a healed chronic ulcer? Regarding the results of gastro-enterostomy, the results were better than they had been; bad results were often due to the maladroitness of the surgeon who produced traction. In a proportion of cases bilious regurgitation followed, and required subsequent treatment to correct. He thought that surgery should acquire a better technique. He had been struck by the good results of extirpation when this had been required.

In resuming the discussion on the second date the Chairman, Professor WALTER HUNTER, referred to the question of a syphilitic ulceration of the stomach, citing a case in which specific treatment was followed by cure, which was demonstrated by x-ray examination. Another case was referred to where there was profuse vomiting of blood, the Wassermann test was negative, but the haemoglobin was only 20 per cent. At present this patient was doing well with rest in bed, and later x-ray examination would be carried out, and if stenosis of the pylorus was present, the question of operation would be considered.

Dr. G. HERBERT CLARK said that until doctors familiarized themselves with the results of physiological research upon the functions and actions of the stomach and duodenum

treatment was liable to be only symptomatic. Why operative interference by gastro-enterostomy very often failed, when there was no marked stenosis and consequent delay and dilatation, was that the emptying of food and acid-juice mixture—not properly triturated chyme—occurred far too rapidly, and intestinal and other troubles followed. The gnawing pain, he thought, was largely due to muscular action; there was an effort by antiperistaltic action to return food unsuitable to the mucous membrane and digestive juices of the stomach. He considered that if the patient took the same care in the way of rest, diet, etc., without operation as he had to take after operation, his relief would generally far outdistance any benefit he would obtain from surgical intervention.

Dr. W. R. JACK said that most physicians agreed as to the type of case suitable for operation, but that surgeons took a wider view. In his experience where, in acute gastric ulcer with hæmorrhage, an operation was performed to tie the vessel, the surgeon invariably failed. In other similar cases ordinary methods of medical treatment had repeatedly succeeded. He asked for late results from surgeons. Most methods succeeded temporarily and sometimes for years, but he wished to know if surgical relief was greater than medical and more prolonged.

Dr. H. E. JONES, as a general practitioner of over twenty-five years' standing, remarked that whereas the physician and the surgeon saw the cases often after long duration, the practitioner saw them at the beginning, during and after treatment. He referred at length to the different types of case—of ulcer and of simulated ulcer—seen by the general practitioner and commented upon the probable effect of the prolonged rest after operation upon the body and mind of the patient. Mr. ALEXANDER McLENNAN was certain that in every case all available measures of investigation into the condition should first be applied. X rays, used for screening and for photographs, as well as chemical methods, were necessary. Where the stomach was posited without pyloric stenosis surgical interference was not indicated, although if an ulcer existed the sufferer was in a most unhappy condition. So also was the patient who after operation suffered from regurgitation of bile with vomiting and distension. He spoke of the method of stretching the pylorus digitally for dilatation of the stomach as having proved satisfactory. When laparotomy was done for perforation, should a gastro-enterostomy be done at the time? His colleague, Mr. William Campbell, usually did not do a gastro-enterostomy at the time, and many cases did very well without any further operation. The Mayos said that a perforated duodenal ulcer, for some unknown reason, healed better than an unperforated one. Ulcer of the duodenum did not heal nearly so well as ulcer of the stomach.

Dr. DOUGLAS RUSSELL said he was becoming increasingly reluctant to advise operation, but believed more in mental and physical rest. Small doses of opium seemed to do good. Mr. ARCHIBALD YOUNG remarked that there seemed to be a purely medical view and a purely surgical one; only by combining these could one arrive at a useful conclusion. From the point of view of the surgeon it might be said that the surgeon had to deal with the chronic ulcer. A proportion of acute cases with perforation or alarming bleeding of course occurred, but the majority were chronic. Therefore he asked whether the statement that a chronic ulcer never healed was or was not true. After all, why should it not heal? Was there anything in its nature different from other ulcers? Could all symptoms disappear, perhaps permanently, and the ulcer still remain? The view appeared inconsistent with the facts of pathology and the symptoms of disease. Few surgeons had not at operation seen evidences of healed gastric and duodenal ulcers. His own experience had convinced him that posterior (no loop) gastro-jejunostomy, without ligature or closure of the pylorus, would give good results in a large proportion of cases.

LEFT-HANDEDNESS.

At a meeting of the Liverpool Medical Institution, held on January 6th, with Dr. J. E. GEMMELL (President) in the chair, Dr. C. J. MACALISTER read a short paper on left-handedness and conditions associated therewith. After referring to some of the theories concerning the hereditary explanations of right-handedness and left-handedness and

the statistics concerning the proportionate incidence of the latter as compared with the former, he indicated that he did not wish it to be suggested that every case of left-handedness was liable to the functional disorders or ataxias to which he directed attention. By far the greatest number of left-handed people were perfectly normal physiologically, but he particularly referred to certain abnormalities which he felt sure depended upon transposed function. He showed a case of a left-handed girl, aged 13½, who was practically aphasic, whose language was one of signs and gesticulations resembling those natural ones used by the deaf. She had a fair amount of intelligence and a wonderful memory, her backwardness depending, to a certain extent, upon simple lack of education. She was being taught to sign and to read and write by the methods adopted among deaf-mutes. Dr. Macalister laid great stress upon ancestral and collateral history as bearing upon the question, and instanced cases of left-handed stammerers having left-handed relations, and of right-handed stammerers also having a left-handed ancestral history. He suggested that these marked inco-ordinations might be related in some way in the left-handed to the right speech centre being unbalanced by some unusual development of function of the left one, thus giving rise to a confusion of co-ordination. The same principle applied to cases of chronic hemichorea. Having noted that although transposition of the viscera might be thought to be associated with left-handedness, this was not constantly the case, there being a good many records of this condition where there had been right-handedness. Undoubtedly, in a certain number of cases, left-handed people had left speech centres, as proved by those cases of cerebral hæmorrhage affecting the right speech motor area where there was no aphasia. He quoted cases described by Foster Kennedy in which injuries involving the right Broca's areas in left-handed people had not been associated with defects of speech, and another series of cases of right-handed people showing similar peculiar results, involvements of the right Broca's areas being associated with aphasia. Kennedy's argument was that where there was a known hereditary or collateral history of left-handedness the speech centres appeared to have been transposed, whereas, in a number of cases of which no such history had been discovered, transposition had not taken place. In all probability there might be a Mendelian explanation of this, and that the occasional incomplete cases as well as the complete ones might be the result of hybrid marriages. The normal physiological inco-ordination depending on handedness referred not only to the general motor system, but it had another curious association, there being normally a strong side and a weak side to the body, a fact which applied not only to physical strength and dexterity, but had a bearing upon vitality and susceptibility to disease. He had frequently demonstrated that not only congenital malformations but also a number of acquired diseases tended to attack the weaker side.

A MEETING of the London Association of the Medical Women's Federation was held, on January 11th, at the Elizabeth Garrett Anderson Hospital, Mrs. FLEMING in the chair. Dr. MARY BELL read a paper on psychological forgetting in relation to lying, giving of evidence, and medical histories. In the course of this she suggested that the tendency to replace accurate by phantasied memories should be considered much more seriously in courts of law. In the recent Greenwood poisoning case a year elapsed between Mrs. Greenwood's death and the final trial. "Which one of us (asked Dr. Bell) could remember the details of any one Sunday in 1919? It is true they might remember events during the evening when it was realized that Mrs. Greenwood was seriously ill, or if the possibility of poison had arisen at once they might have reconstructed the events of the earlier part of the day and kept them in mind, but as far as we know there was no intensity of feeling attached to the forenoon of that day. Any evidence given for the first time six to nine months after Mrs. Greenwood's death as to whether Mr. Greenwood went into the pantry or not, or as to who drank wine on that particular Sunday, must, to my mind, be pure phantasm." A remarkable instance of phantasied memory occurred also in the Tichborne trial where the claimant was accepted from the first as her son by Lady Tichborne, though he differed completely from him in physique, in way of speech, and though she even recognized that the account he gave of past events was very confused and differed from her own. Dr. Bell's paper was followed by a short discussion, in which Dr. HELEN BOYLE, Dr. PAXF, Dr. BRISCOM, Dr. LOWRY, and others took part.

Reviews.

A STUDY OF THE LONG BONES OF THE ENGLISH SKELETON.

The Department of Applied Statistics of the University of London has issued the first two sections of Part I of *A Study of the Long Bones of the English Skeleton*.¹ It deals with the femur. The authors are Professor KARL PEARSON and JULIA BELL, and the work is published as the tenth biometric series of the Drapers' Company Research Memoirs.

In his prefatory note Professor Pearson tells us that the work was started twelve years ago merely with the intention of illustrating the application of biometric methods to a special field of anthropometric inquiry. During these twelve years, however, biometric methods have come into more general use, though the author thinks there still remain anthropometricians who believe elementary arithmetic adequate for their science. If such there be, or if Professor Giuffrida-Ruggieri still thinks as he thought in 1905, that English anthropology, being merely descriptive, no longer counts in science (quoted by Pearson), these volumes must surely convince them of their error.

Karl Pearson is a world-wide authority on statistics, his methods are standard, and in his application of them to the present subject he conveys the impression that the truth and nothing but the truth is what he seeks, and moreover that by these methods of mathematical exactitude it will be found. That statistical work "is absolutely primary and the only safe road to generalization" is the authors' contention. After reading these volumes, the reviewer will be unable to accept conclusions unsupported by a statistical presentation of the case. "School-boy arithmetic," which draws conclusions from percentages based on small numbers, and without appreciation of the probable error, will no longer suffice. Throughout the work, whatever the point in debate—the source of the normal bowing of the femur, or the lines of evolution from the anthropoids to recent man, or whether woman be more ape-like than man (a charge the authors find non-proven)—the facts are clearly stated and assessed at their mathematical value, often in the form of a tetrachoric correlation accompanied where needful by the probable error.

From all this it will be gathered that the English long bones are not the only subjects of discussion in these volumes, and the authors admit that as the twelve years went by they found the ever-widening interest of their subject carrying them ever further afield till their essay was becoming a monograph on the primate long bones. They tell us, indeed, that they regretted not having begun with the femur of the lower primates, for then they would have known better what anomalies of the human femur (such as a posterior fossa) to look for, and what measurements would have been found suitable or unsuitable for comparisons. Some measurements, such as the pithecoid index and indices found on the direct and oblique lengths of both condyles (not hitherto taken on the human subject), were found eminently suitable; others, such as the platymetric index taken in the subtrochanteric region, quite unsuitable, owing to the varying position of the maximum flattening. The authors apologize, too, for the want of balance this widened interest has given to the monograph, since in the case of one species (man) 80 to 100 characters have been determined on the femur of 800 skeletons, whereas it has been impossible to obtain an equivalent series of any other species. Material and, later, owing to war exigencies, time and workers were wanting. The scientific public assuredly will not regret this widened scope, and they will sympathize the more with the authors in their plea for a general use of standardized femoral measurements for better use of rare material—the measurements of such a treasure as the Trinil femur are still unpublished—for more material, sexed and complete if

possible, but at least that collectors should remember that other bones besides the skull are worthy of storage in a museum.

The first five chapters are illustrative of the application of biometric methods to the study of a single long bone. They deal with measurements taken; anomalies of the femur; the typical English femur, its comparison with that of other races; variability of the English femur, its comparison with that of other races and of other bones, and the influence of side and sex. In Chapter I it is noteworthy that "maximum length" is more closely correlated with stature than "oblique length." In the chapter on sexing it is shown that there is a very close agreement between anatomical sexing and mathematical sexing, though the latter is proposed only as a control. To test the sexing value of any measurement, overlapping Gaussian curves (a dichotomy) of this measurement taken on an approximately equal number of male and female bones are made, and if the distance from the male to the female mean be about twice the standard deviation of one or other sex the measurement may be regarded as useful. The authors note that since the sex differences are often less than the racial differences, mathematical rules for sexing must be deduced afresh for each new series. Under "anomalies" we find a most interesting discussion on the third trochanter and the gluteus maximus, in the course of which the third trochanter is exonerated from being a stigma of degeneration.

In fixing the type of the English femur the authors found great difficulty in utilizing the work of others, owing to want of standard measurements, selection of too few characters for measurement, and the small numbers dealt with. Nevertheless, an extensive table is given of the means (with probable errors) of English femoral characters, and a comparison with those of other races. The authors suggest that the defect of obliquity and torsion, and the excess of antero-posterior dimensions of the right femur are an associated system, and embrace the main differences of size and form between right and left bones; and dealing with the influence of sex they note that as far as their data for the femur go they do not confirm the views that have been propounded by certain authors that the sexes differ by arrested development, or that one sex is more primitive or more ape-like than the other. Examination of the comparative variability of the sexes shows that the female femur is slightly more variable than the male in civilized races in spite of the greater fixity of the proximal epiphysis and in contradistinction to certain vigorous writers.

Chapter VI opens with a remarkable table of 344 of the chief correlations of the characters of the London femora, followed later by a table of the differences of male and female correlations. In the discussion of these tables the interesting point is emphasized that the mean projection of the centre of the head of the femur beyond the mid-trochlear point on the mesial side is in the male four and in the female three times larger on the left than on the right side, and the widened scope of the monograph becomes apparent in references to evolutionary changes and Mendelian units.

Chapters VII to X, comprised in Section II, deal with the general and diaphysal femoral characters in man; the comparison of the femur of man with the femora of other primates; characters of the epiphyses; examination of the dwarf femur; comparison of the femora of the anthropoids, of primogenial man, and of recent man. In Chapter VII we meet with the pithecoid index ($100 \times$ trochanteric oblique length / oblique length), introduced as a means of inter-species comparison of the relation the tops of the great trochanter and of the head of the bone bear to each other (in man the head of the bone is at a higher level, in simian femora the top of the great trochanter is at the same level or even higher), and it is found that for this character *Pithecanthropus erectus* is essentially modern man. Indeed, for all characters the authors have been able to study the femur of *P. erectus* (the Trinil femur) is recent human. From the same study of general femoral characters the authors conclude that the human femur has a troglodytic rather than a hylobatic origin—that is, man is nearer the greater anthropoids than the gibbon, *qua* his femur.

The interest of the work now frankly centres round the descent of man. Every point is examined with mathematical exactness, and since the authors have made use of the work of others they have been led to scrutinize their

¹ *A Study of the Long Bones of the English Skeleton*. By Karl Pearson, F.R.S., and Julia Bell, M.A. Drapers' Company Research Memoirs, Biometric Series XI. Part I, Chapters I to VI, The Femur. Part II, Section II, The Femur of Man, with Special Reference to other Primates. London: Cambridge University Press, H. L. Lewis and Co., and William Wesley and Son, 1919. (Pp. 559, with illustrations and diagrams, accompanied by atlas to Part I, 59 plates and table, and atlas to Part II, 44 plates and 2 tables. Text and atlas, Part I, 30s.; text and atlas, Part II, 40s.)

figures with the same care. Only too often, as with the collar angle (Chapter VIII), which is given by one authority as 119 degrees and by another as 130 degrees for the Australian aboriginal, want of standardization makes the figures almost worthless. Yet, in despite of all difficulties, reasoned conclusions are reached, and in the succeeding chapters there is unfolded a scheme of the descent of man based on mathematical examination of the evidence of the femur.

In discussing the distal epiphysis (Chapter IX), under consideration of the rotular index (measuring roughly the ratio of articular surface height to breadth), the authors make the point that if the long-tongued patellar articular surface be associated with the power of spring, then a big factor in the history of the evolution of the primate femur is the replacement of this power of springing by power of upright gait. In this respect the measurements of recent man show that as compared with Neanderthal man he has recovered some of the ape power of spring, and is in this character reverting to the ape.

In their own mathematical researches into the pedigree of man the authors have made no use of size, but have dealt only with indices. The method is described in Chapter X, and leads to most interesting results. What the authors call mean indicial deviations, deduced from the reduced indicial deviations of (1) the general indices of the femur, (2) the indices of the shaft, (3) the indices of the "bust," (4) the indices of the distal epiphysis, and the mean indicial deviation of (5) all the forty indicial characters concerned in the above, are used to plot five corresponding radial diagrams showing the relation for each set of indices and for the pooled indicial characters of recent man, Neanderthal man, *Pithecanthropus erectus*, *Dryopithecus*, orang, gorilla, chimpanzee, gibbon, and in some cases Tarsius, to each other and to a central simio-human point and axis. The general result is that recent man is far the closest to, and the gibbon and gorilla the furthest removed from, the simio-human mean in femoral characters. This result is in accord with the conclusion the authors reach from a consideration of the anomalies of the femur. The prot-simio human femur is expected, when found, to have human *plus* chimpanzee, and not *plus* gibbon, features.

The authors recognize that this is a bold deduction from the study of a single bone, but they plead that the chief aim of this monograph has been and will continue to be the discovery of how much can be ascertained from the intensive study of single bones. There is more to come—studies of the humerus and tibia—but workers are few, expenses enormously increased, and material often difficult to obtain. Every one who has read these volumes will sincerely wish the authors may overcome their difficulties. To cease, or even curtail, such publications would be a scientific disaster.

Throughout the work tables of measurements, indices, ratio-, means, comparisons, are given wherever necessary. They form, indeed, a large part of the printed matter, and the authors have spared themselves no trouble in their desire to exhibit clearly the groundwork of their argument. There are three short but interesting appendices on the correlation of the femoral characters in man, femora of fossil lemuroids, and the sesamoid bones of the knee. The bibliography is a standing testimony to the authors' thoroughness in seeking and appraising the work of others. Each of the two sections is accompanied by an illustrative volume, chiefly photographic, and of great excellence. The atlas to Section I is accompanied by a table of all the measurements made on the London bones, that to Section II by two tables of measurements and descriptions of femoral characters of the primates (man, anthropoids, lesser apes, and lemuroids), which by themselves are works of reference.

We heartily congratulate the authors on their great achievement, and the Drapers' Company on the wise use made of their funds.

J. G. TURNER.

PSYCHONEUROSES OF WAR AND PEACE.

During the war the problem of functional nervous conditions more or less forced itself on the notice of Dr. MILLAIS CULPIN while he was engaged upon work as a surgical specialist. He fortunately realized the functional element in many of his surgical cases, and the interest of

the psychoneuroses led him subsequently to devote all his energies to this branch of medicine. The experience he thus gained is recorded in his book on *Psychoneuroses of War and Peace*.² It is clear that the views herein developed have been gained from personal observation and in close contact with clinical material. Dr. Culpin feels his way carefully. He keeps the therapeutic aim always in the foreground. He is cautious in accepting theories, and he only does so in so far as they harmonize with facts he has observed for himself. In the preface he indicates that one object of his book is to discuss the bearing of the theory of the unconscious upon psychoneuroses found in soldiers. In summarizing his views Dr. Culpin says he finds that the existence of repressed but activating memories renders the theory of the unconscious "necessary to the understanding and treatment of the neuroses." A certain reluctance seems to be evident in this admission, and it may be that he would be glad to find some formula, expressed in terms of the "organism as a whole," which would serve to replace the no doubt necessary but somewhat unsatisfactory concept of the unconscious. The trend of psychology in certain directions would seem to justify the hope that such a formula may ultimately be found. Since Dr. Culpin only accepts this fundamental hypothesis after careful consideration of the facts before him, it is not surprising to find that he does not give full adhesion to any of the more specialized schools of thought.

The inclusion of psychasthenia in his classification indicates a conservative attitude. In this we think he is wise. In spite of the tendency to split up this clinical group the necessity for such a procedure is doubtful. At the risk of being regarded as old-fashioned we would express the opinion that Janet's psychasthenic group is a most useful clinical concept, and it might well remain more or less as he defined it. Furthermore, the broad biological generalization which he formulated in regard to the protective character of neurotic symptoms has been abundantly demonstrated as true of the war neuroses, and the influence of his views tends to become increasingly apparent, though they have, of course, been illuminated by more recent developments.

Dr. Culpin finds it necessary to explain the phenomena of the psychoneuroses by reference to the censor. This term has been much criticized, and on grounds which appear reasonable. It is not easy to accept this concept with any degree of satisfaction, and such phrases as "the Censor is firmly entrenched in the unconscious" and "the Censor is clever at hiding his work" are assimilated with difficulty. Such an artificial explanation of a natural biological process stands in obvious need of revision.

A certain number of cases are here grouped under the heading of "Weak herd instinct." The reference is to those cases in which "the sense of discomfort or fear was always present in the consciousness" and in which personal interest overcame patriotism. We recall that Dr. S. I. Schwab found it useful to define a somewhat similar group under the heading of "Timorousness or state of anxiety."³ In regard to treatment, the author follows no hard-and-fast lines, but bases his general treatment upon the revival of repressions. He gives an account of his technique, and then devotes attention to dreams, phobias and obsessions, hysterical fits and epilepsy, stammers and tremors, gross amnesia and pathological irritability, and these symptoms are illustrated by reference to actual cases. The book will be found of interest and value to those who are concerned with the care and treatment of the still large number of nervous pensioners.

ANGINA PECTORIS.

MR. WALTER VERDON's work on *Angina Pectoris*⁴ contains a mass of material and interesting accounts of cases more or less illustrating his views, on which he has already published many short communications. The later pages of the volume are devoted to other papers, especially to the subject of "Protective Reflex Action" (Appendix I). One of the great questions discussed in the book is the association of angina pectoris with gastric disorders and

² *Psychoneuroses of War and Peace*. By Millais Culpin, M.D. Lond., F.R.C.S. Eng. Cambridge University Press. 1920. (Demy 8vo, pp. 127, 10s. net.)

³ *The War Neuroses as Physiologic Conservations*. Dr. Sidney I. Schwab. *Archives of Neurology and Psychiatry*, May, 1919.

⁴ *Angina Pectoris*. By Walter Verdon, F.R.C.S. Brighton: W. T. Moulton and Co. 1920. (Demy 8vo, pp. 422; 8 figures.)

"windy stomach." The main facts on this subject are well summed up in three passages quoted by the author from Sir Clifford Allbutt:

"Dilatation of the stomach by some processes of sympathy or exhaustion may be induced by angina pectoris; it is frequently associated with it. Broadbent and myself made this observation, and so before us did Elsner explicitly. We have noticed that eructation often signifies relief." "If gastric ectasis is not to be reckoned as a correlated symptom of angina, the coexistence is by no means to be overlooked, as the mere oppression of it may provoke the recurrence of seizures, or even determine the moment of death." "Whatever the nexus, whether a vagus reflect from heart to stomach, or a mechanical butting at the heart itself, we are not yet in a position to say. Every day experience tells us that cardio-aortic maladies are mitigated by rules of diet which guard against generation of wind in the stomach, and are relieved by cordials which expel it, when there."

Mr. Verdon himself (p. 51) remarks:

"The really important questions to explain are, not as to how gas gets into the stomach, but when there, how does its presence initiate and sustain seizures, and how comes it to pass that the wind and pain are discharged together?"

For the author's explanations in answer to these questions we must refer readers to the book itself. Sir Clifford Allbutt has adduced evidence to show that death in angina pectoris results from vagal inhibition, and Mr. Verdon explains the infrequency of death during seizures (p. 66) as a paradox due to the activity of sympathetic centres inhibiting activity of vagal centres. In support of the view that exhaustion of the reserve contractile power of the heart is not necessarily the causal agent of angina pectoris, he adduces the example of a patient walking ten miles just after several seizures. He also confirms Allbutt's summary, "that disease of the coronary arteries does not set up angina is an axiom founded on universal experience." Mr. Verdon, however, concludes (p. 81):

"It is thus gathered from statistical evidence that the effect of coronary disease on the causation of the angina pectoris is nil; nevertheless, its influence in determining a fatal issue when angina is present is great—a myocardium impoverished through the attenuation of its nutrient supply soon falls victim to vagal inhibition."

He likewise argues that disease of the aorta, although a causal agent of the segmentary neurosis manifested by attacks of angina pectoris, is not the predisposing nor yet the exciting cause of seizures. In Auscher's case the necropsy showed definite signs of old pericarditis, while the aorta was quite healthy. In regard to high blood pressure, he refers to patients in whom a brachial systolic blood pressure of 200 to 300 mm. Hg during ten to fifteen years has not provoked a single attack of angina pectoris. According to Mr. Verdon the predisposing cause of anginous seizures is most probably a segmental neurosis.

The book, which is the outcome of much observation, thought, and long-continued attention, should be in the hands of those interested in the various doubtful questions connected with the subject of angina pectoris. The usual sites of pain and the other symptoms are especially carefully discussed. The local roughness and induration of the skin produced by frequent scratching in certain anginous subjects (p. 46) is surely what is now generally known as local "lichenification," and is not at all directly connected with angina pectoris. The use of the term hysteria, on p. 339, is rather confusing: "A very mild type of segmentary neurosis passes under the name hysteria. In this instance the uterus is primarily at fault."

ROENTGENOLOGICAL METHODS.

The scope of *The Principles and Practice of Roentgenological Technique*,⁶ by Dr. I. SETH HIRSCH of New York, is strictly limited, and questions of x-ray diagnosis do not come under consideration. The object of the author is to put before the student of roentgenology only those principles of technique which will serve him best on the difficult road to the goal, roentgenological diagnosis and therapy. With this object in view it is not too much to say that he has entirely succeeded. The whole book teems with information of the greatest possible value, presented in a lucid and practical manner; the explanations

are expressed in language easily read and understood, and a large number of illustrations serve their part in making the text quite clear. Of its two main parts, the first considers principles of technique, describes all the apparatus generally in use, explains its purpose and the ways in which it is employed, and gives a fair amount of information on the physics of radiography. The second part deals in the main with descriptions of position for the patient and the x-ray tube for each variety of x-ray examination; in each case a photograph is given, and makes everything clear to the eye. Reproductions of radiographs side by side with these photographs indicate the results of the actual exposures. There is a useful chapter on the principles which guide times of exposure, and, amongst other points, reference is made to the influence of the size of the part to be examined and the sensitiveness of the plate; an elaborate set of exposure tables which furnish every detail are given. There is a chapter on development and the dark room, and another on the x-ray laboratory. The latter gives diagrams of the arrangement of apparatus which will be of value in fitting up a hospital or a private installation. The book is remarkably well printed and the numerous illustrations, whether diagrammatic, photographic, or radiological, are of the highest merit. The student of radiography will find this a textbook of great value, the expert and experienced worker cannot fail to appreciate its merits as a book of reference.

NOTES ON BOOKS.

THE eighth annual conference of the National Association for the Prevention of Tuberculosis was held in St. George's Hall, Liverpool, on October 7th, 8th, and 9th, 1920. A summary of the proceedings appeared in our issue of October 16th, 1920, at p. 603. The full official *Transactions*⁶ of the conference have now been published. The papers are grouped under three headings: (1) Review of methods of prevention and treatment of tuberculosis advocated from time to time, the extent to which they have been followed, and the results obtained. (2) Practical difficulties in connexion with the carrying out of tuberculosis schemes and the best measures to overcome them. (3) Milk as a source of infection, and the preventive measures to be employed. The volume is well printed and contains much of interest and importance.

DR. NOEL BARDSWELL'S little *Handbook for Tuberculosis Workers*⁷ discusses, in non-technical language, the causes of tuberculosis, its manifestations and treatment, and the methods of antituberculosis administration. It is distinguished not only by clearness in scientific exposition, but by sound common sense on such important points—usually overlooked—as the adjustment of financial troubles and the remedying of insufficient income in small households when the wage-earner is stricken down by ill health.

The fifth edition of Dr. CHARLES PORTER'S *School Hygiene and the Laws of Health*⁸ contains some new matter which adds very much to its usefulness. In the chapter on infectious diseases an account is given of bacteria and the manner in which disease is spread, and the expression "carriers" is well explained. There are three entirely new chapters respectively with medical inspection of children, welfare of infants and of special schools. A good deal of accurate information is included in the three pages devoted to special schools, in which open air schools, school camps, nursery schools, and cripple schools are referred to. The chapter on sanitation and cleansing is one which should be of great use to teachers and school managers. Few will disagree with Dr. Porter in his condemnation of trough closets for schools, a condemnation it may be observed which appeared in the first edition of his book in 1906. We are unable to endorse his apparent approval of "ash closets," in which riddled ashes are used. Earth has a nitrifying action upon excreta, but ashes are sterile, and cannot therefore have any such action.

⁷ *Handbook for Tuberculosis Workers*. By N. Bardswell, M.V.O., M.D., F.R.C.P. London: J. Bale, Sons, and Danielsson, Ltd. 1920. (Post free, pp. 70. 1s. 6d. net.)

⁸ *School Hygiene and the Laws of Health. A Textbook for Teachers and Students in Training*. By Charles Porter, M.D., B.Sc., M.R.C.P. Edin. Fifth edition. London: Longmans, Green, and Co. 1920. (Cr. 8vo, pp. 381; 117 figures. 6s. 6d.)

⁶ *Principles and Practice of Roentgenological Technique*. By I. Seth Hirsch, M.D., Director of X-Ray Departments, Bellevue and other Hospitals, New York City. New York: The American X-Ray Publishing Co.; London: H. K. Lewis and Co., Ltd. 1920. (Cr. 4to, pp. 264; 311 figures; 22 tables. 60s. net.)

All workers in chemical pathology will be greatly indebted to Professor CAVAZZANI for his excellent little book on the proteins of the urine. The first two chapters are devoted to a qualitative description of the proteins found in the urine. This is followed by an excellent account of all the latest methods for the quantitative estimation of the various urinary proteins, and full justice is done to the pathological implications of the subject. A very useful analytical chart is appended. The bibliography is exceptionally complete, and the monograph will save much time and trouble to research workers.

Le Proteine dell' Urina By Emilio Cavazzani Ferrara 1920 (Pp, 163)

APPLIANCES AND PREPARATIONS.

Surgical Needles

Mr. BRIDEN GLANDING, M.S., F.R.C.S. (Aspley Guise, Beds.) writes: Some six years ago Messrs. Allen and Hanburys made for me both round pointed and cutting curved needles with square bodies, to my special measurements, in sizes 9, 12, 15 and 15 fine. The ordinary curved cutting needles are usually made with either a flattened or too weak a shaft, so that in the smaller sizes they are often unequal to the strain put upon them. They are especially liable to break when used

in dense fasciae, scar tissues and particularly in the cervix uteri, with annoying consequences. The round pointed surgical needles usually supplied have always suffered from the disadvantage that having round bodies, they tend to turn in the needle holder. The square body obviates this, and, while in no way affecting their general utility, makes it possible to use them in all except fascial structures with much less injury to tissues and vessels than with cutting needles. Six years' continuous use of these needles has impressed upon me their advantages, and suggests to me that if known they would be extensively used. They should have ordinary eyes, with the exception of No. 15 fine, which is spring eyed and used for gut work.

An Improved Mouth Gag

Major K. BRICK, F.R.C.S. Eng., surgeon to the Welsh (Ministry of Pensions) Hospital, Netley, sends us particulars of a new mouth gag, which has been made by him. It is made from the tooth plates and allows the gag to be inserted and removed easily and quickly, even when the jaws are tightly closed. Anaesthetists will recognize that this non-cutting knife edge will prevent a delay which often is fraught with serious danger to the patient. In dental extractions it is found that with this gag the prop which is generally used becomes unnecessary. At the posterior and inner edges of the tooth plates are ridges or lips, which effectively prevent the gag from slipping forwards and outwards when the mouth is forced open. (There are no

ridges at the anterior or outer edges for the gag, when opened, does not tend to slip backwards and inwards.) The mouth can be locked in the open position, so that the hand of the anaesthetist does not have to hold the gag once it is in position—an important advantage. The angles and length of the gag are so arranged as to give the greatest leverage possible combined with lightness and strength. The handle is broad and concave, and facilitates the action of the hand in opening the gag. There are no serrations on the ratchet, allowing the gag to be fixed open in any desired position. The spring is detachable to facilitate cleaning. It is unnecessary and undesirable to use rubber to cover the tooth plates. The gag is made by and can be obtained from Messrs. Down Brothers, St. Thomas Street, S.E. 1.

Solid Neutral Red.

Messrs. BURROUGHS, WILCOX and Co. have added to their series of compressed microscopic stains a "solid" brand of neutral red. Each 0.1 gram product dissolved in 10 c.cm. of distilled water gives a 1 per cent. solution. Neutral red is used for Gram's stain, and more particularly for Jensen's modification, also for Neisser's stain. These solids are very handy for the quick preparation of microscopical stains in small quantities as required.

THE HOSPITAL PROBLEM.

BY

STANLEY RAW, M.D. DURH., F.R.C.S. EDIN.,
SURGEON, 107A INFIRMARY, GLENDELL LANE

THE present voluntary hospitals are no longer voluntary in the sense for which they were ordained—namely, for the gratuitous treatment of the sick and lame poor—and the principal cause of the departure from original foundations has been the great widening of surgical scope in the past twenty-five years, so that—as is common knowledge—multitudinous cases are now operated upon in which operation would never have been suggested a quarter of a century ago. The natural result of this extension of scope is a greatly increased demand for its benefits, and in the main these can only be supplied in hospitals or nursing homes—in the former gratuitously, and in the latter at a prohibitive cost for the great bulk of the population.

To meet in some way the expenses of these new demands a system of workmen's contributions was introduced into many hospitals, and although in theory these contributions are considered to be personal donations to the charity, in actual fact they have come to be construed as being a sort of insurance premium, and the donors and their dependants are looked upon as having the right of admission, without further payment, to the hospital to which they subscribe, altogether irrespective of their financial position. In short, many voluntary hospitals are no more and no less than workmen's co-operative institutions where the regular subscribers—and, save in emergency, no others—are admitted without further question.

I have no quarrel with this attitude. When workmen's subscriptions were first instituted they were given in the truest spirit of charity and generosity, and with the genuine idea of supporting a charitable institution which was doing good work for the poorer members of the community. Neither do I believe that there is any large degree of avoidable hospital abuse existing, at least in my own district. After all, the most unfailing law is the law of averages, and so far as my judgement goes I am convinced that every class of the population can be divided up into three categories: A small percentage of members is much above the average in intellect and character. Another small percentage is much below the average level in these respects. The third, large class, is composed of straightforward honest people, who want a fair article or fair service for a fair price.

I consider that there are very few people who have an operation done in hospital simply to escape paying a fee, and I am convinced that the majority of patients would gladly pay a fee provided that it can come within the range of their means, and further, their pride resents it being done for nothing. The position of the non-manual workers of the population who, despite the fact that they are in many instances no better off than the manual workers, have to go to nursing homes, need not, I think, be elaborated.

The last point I wish to mention before coming to my ideas of the best future for hospital treatment is the great increase in the amount of work and time that is demanded of the honorary staff. I confine myself to my own hospital. I now have the privilege of being an honorary surgeon to the hospital in which I was a house surgeon fifteen years ago. There has been practically no increase in the number of beds, and nothing beyond the normal increase in the population, and yet the amount of work, as judged by the number of abdominal operations, has increased by 600 per cent.

I shall, I take it, be on common ground when I say there are three methods by which the hospital work of the country can be carried on.

- A. Voluntary hospitals
- B. Hospitals supported out of public funds
- C. Paying hospitals

It is, of course, for the majority of the community to decide which of these methods they prefer. Here I wish to point out for their guidance what in my opinion these various methods mean and entail. I say nothing more about the value of my opinion than to mention that I was a house surgeon for nearly four years, I have been an honorary surgeon for nine years, I served as surgeon to a hospital in France for nearly four years; I was, whilst waiting for surgical work, a general practitioner, and I am now a consulting surgeon perfectly content with my own individual lot.

The Voluntary Hospital.

All of us who have had anything to do with hospital work are attached to the voluntary system in general, and

our own hospital in particular, for it is the centre of our happiest professional associations, and we would gladly carry on in the old way. We cannot carry on in the old way—for two definite sets of reasons. The first set of reasons has to do with the general expenses and necessities of hospital work, and amongst other things includes:

1. The greatly increased range of modern medicine and surgery, with all the extra work and expense attached to the necessary technique, methods, and special departments.
2. The greatly increased number of patients requiring treatment.
3. The greatly increased resident staff necessary to carry out the work.

The second set of reasons has to do with the visiting staff, and includes:

1. The appointment of various officers, such as anaesthetists, pathologists, x-ray specialists, etc., who, in the nature of things, must receive some financial remuneration for their services.
2. The greatly increased amount of work required from the regular honorary staff and the much higher standard demanded in this work.
3. The consequent greater difficulty for the honorary staff to find a sufficient source of income without engaging in general practice.

I, like most other surgeons of my acquaintance who have formerly been in general practice, am very glad indeed that, of necessity, I had that experience, but apart altogether from its science, the art of modern surgery is now such that it cannot be as efficiently carried out when the performer has to make his living in general practice as when he can devote his whole time to surgery, when, in fact, his surgical work is made a side line rather than the real business of his life.

If the above two sets of reasons are correct, the continuance of the present voluntary system becomes almost impossible, because:

1. It entails an expenditure which is hardly likely to be met by purely voluntary subscriptions, and which it is not altogether desirable should be so met; and,
2. It necessitates the bulk of hospital surgeons remaining in general practice.

Hospitals Supported out of Public Funds.

A hospital entirely supported out of public funds would necessarily have a paid staff, and in all probability the work of the staff would be confined to the hospital itself, and the benefits of their services restricted to the class eligible for admission to the hospital. The cost of maintenance would be greatly in excess of the cost of the present hospitals. The importance of the administrative side would be enhanced, and the importance of the clinical side would be diminished.

For these and many other reasons along similar lines, I am opposed to the establishment of hospitals entirely supported out of public funds.

Paying Hospitals.

As will be fairly obvious from my previous remarks, this is my view of the solution. To put it into one sentence my thesis is, "Medical or surgical requirement, and not poverty, should be the qualification for admission to the hospital." I therefore advocate that the benefits of the hospital should be made available for all classes of the community that it serves, and that the only necessary qualification for admission should be the possession by the patient of some malady or injury requiring more than "ordinary medical attendance." Between certain limits all patients would pay for their treatment; the necessitous poor would be lodged, boarded, and treated free of charge; the moderately well off would pay the cost of their treatment, and the well off would pay such a sum as would leave a profit to the hospital. I venture to think that if such a system were instituted, the hospitals could actually be made to become self-supporting. I shall not now occupy any more space in working out this system in detail, for it is time enough to consider details when broad principles have been decided upon, but I should like to assist the adoption of these broad principles by advocacy from the following points of view:

1. *Efficiency and Expedition of Work.*—All hospital surgeons have performed operations in three places—their hospital theatres, nursing homes, and private houses—and all will agree that they do their work best in hospital and all will agree that they do their work best in hospital and least well in private houses. Nor is this to be wondered at. In hospital they have their regular assistants, house-surgeons, and theatre staffs, all of whom know their ways and dovetail into the various stages of the operation. In addition to this, they have to their aid the elaborate apparatus of a large well-equipped hospital. If these advantages are admitted as to the art of their craft, how

much more are they evident on the scientific and nursing sides of their work, when the opinion of physician, pathologist, x-ray specialist, can be obtained under the most favourable circumstances, and where the surgeon sends his cases back to his wards knowing that his nurses know almost as much about the after-treatment as he does himself. I do not mean for one moment to suggest that perfectly satisfactory results are not obtained in nursing homes and private houses; what I suggest is that in hospital the surgeon feels more certain that these results will be obtained, and he is therefore easier in his mind, and consequently a better craftsman. The greater expedition of work in hospital, I am sure, needs no further proof than is afforded by the number of cases a surgeon will do in one session at the hospital as compared with his lists elsewhere.

2. *Financial Benefit to the Community.*—There are four classes of patients who may have to be submitted to severe operations or complex medical treatment or investigation:

(a) The poor who can pay nothing, and who have been, are, and should continue to be, admitted to hospital without any personal payment, and for whose treatment voluntary subscriptions will still be needed.

(b) Those who can pay small fees; and who, in virtue of work, etc., are eligible for admission to their practitioners tell me that they have any who could afford £10, £15, or £20 for an hat that sum included the whole cost of nursing, operation, and attendance, but who simply cannot afford the necessary cost of nursing homes. They further tell me that the majority of these patients would prefer to pay, and would welcome the opportunity to do so.

(c) Those who can pay small fees, but who are not eligible for admission to hospital in virtue of workmen's contributions, etc. This is, of course, the hardest hit class of all, and a serious operation in such a family is not only a surgical anxiety, but almost a financial disaster. It is, above all, the class that would rejoice at the opening of hospitals to their kind, where their nursing would cost them less than in a nursing home, and where surgeons could obviously afford to operate for much smaller fees than they are compelled to charge in a private home or house.

(d) The well-off, to whom the actual monetary cost is of little moment, but whose gain would be considerable from the point of view discussed in the next section.

3. *Economic Benefit to the Community.*—This will best be seen if I limit my argument to the consideration of surgical emergencies. How many acute surgical emergencies occur daily throughout the length and breadth of England I do not know, but the number must be considerable, even though we limit our definition to ruptured gastric or duodenal ulcer, intestinal obstruction in its many varieties, acute fulminating appendicitis, and similar impending calamities. What happens to a patient so afflicted? The "hospital class," if seen early enough by their own family doctor, can be immediately sent to hospital and operated upon within two or three hours of the first symptoms, and under no other circumstances can the operation be achieved. We therefore have now which the most skilled, industrious, and useful members of the community have a worse chance of recovery from a serious surgical emergency than have the least useful members. As individuals no one person has any more right to medical or any other benefits than another; but surely the time has arrived when the highly trained professional and business classes should be given an equal chance of recovery with the least skilled labouring classes. Therefore, open the hospital doors to them and let them get more quickly back to their places in the economic machinery than they are at present able to do.

4. *The Position of the Hospital Staff.*—This would be altered in many ways. Financially the more successful members would probably be less well off, but their scientific position would be so much more comfortable that any loss of income would be more than compensated for. I would suggest that the staff should receive a small retaining fee for their work in connexion with the non-paying patients, and that their remuneration for attendance upon the paying patients should be a matter of arrangement between them and the patients. The important thing is that the members of the staff would be restricted in their practices to their own particular variety of work, and, further, that they would only practise their own specialities as consultants. The benefits from this arrangement are too obvious to need tabulation, and they are so obvious that it is a matter of surprise that they have not already been secured.

5. *The Retention of the Spirit of Charity.*—This seems to be the basic thought behind the objections of those who most insistently demand the retention of the voluntary system as at present constituted. The spirit of charity

As a result of scientific investigations begun in 1914, improvements have been carried out at Harrogate, and the strength of the saline sulphur bathing water, has been doubled; the strength of the other sulphur bathing waters has also been increased. The Harlow Car alkaline sulphur water, which is used for skin diseases, has been brought in an efficient state to Harrogate from the springs over two miles distant.

SATURDAY, JANUARY 22ND, 1921.

THE VACCINATION OF CATTLE AGAINST TUBERCULOSIS.

VARIOUS attempts have been made to render dairy cattle immune to tuberculosis, but without any great success. The most promising results were obtained by the use of attenuated strains of tubercle bacilli. For several years previous to the war Calmette and Guérin had been publishing studies in this line, but these never attracted the attention which they merited. In 1913 they showed that by cultivating the bovine tubercle bacillus, in a long series of successive passages on a potato medium treated with glycerin and ox-bile, they obtained an attenuated strain of bacilli not virulent for the ox, monkey, and guinea-pig, and well tolerated by the body, even when injected intravenously in considerable doses. In the case of cattle so treated a marked resistance to intravenous inoculation of ordinary tubercle bacilli developed a month after inoculation. Intravenous injection of 100 milligrams of the seventieth subculture into a calf produced a general reaction, from which the animal recovered spontaneously after fifteen to twenty days; in other words, the tubercle bacillus was so modified that it became non-tuberculinogenic, though it remained capable of provoking abundant antibodies and agglutinins in the serum of the injected animal. Animals so treated were unaffected by intravenous injections of 3 milligrams of virulent bacilli.

The conditions under which dairy cattle live, however, and the way in which they naturally contract tuberculosis, prevented any confident conclusions from being drawn regarding the efficacy of the protective inoculation against naturally acquired tuberculosis. Calmette and Guérin, therefore, set about the investigation of this question towards the end of 1912, but their experiments were rudely interrupted by the German occupation of Lille, and the repressive measures adopted by the German authorities finally brought them to a close in the autumn of 1915; they were, however, only able to publish their results a short time ago.¹

They employed ten Breton heifers, from nine to ten months old, which were free from tuberculosis. Six of these were vaccinated with the living attenuated tubercle bacilli, and four were kept as controls. In November, 1912, the six heifers received into the jugular vein a single injection of 20 mg. (880 million) of bovine bacilli from a fortnight old culture of the seventieth generation on bile-potato medium. On that day all the heifers, inoculated and uninoculated, were placed in a cowshed specially arranged to favour natural contamination; this shed had already been occupied for two months by five tuberculous adult cows. In order to ensure contamination the tuberculous cows were stalled in front of the row of heifers and the floor of the shed was so inclined that the dejections of the former constantly soiled the bedding and the food of the latter. Some of the tuberculous cows died, but were replaced by others also tuberculous, so that there were always five infecting cows present;

altogether ten such cows died, in eight of which autopsy revealed the existence of advanced tuberculosis, and in the other two only a discrete tuberculosis of the bronchial and mediastinal glands. One of these last remained in the cowshed for a period of thirty-one months, so that the minimum effective infecting number may be put at three—all serious cases present at the same time.

A year after the beginning of the experiment the ten heifers were given an injection of tuberculin. The result of the test was that three out of the four controls reacted positively, and of the six vaccinated, one was positive, two were doubtful, and three were quite negative. But there is more in this than appears at first sight. It is quite permissible to conclude in favour of tuberculosis in the case of the untreated animals, but another factor has to be considered in the interpretation of the positive and doubtful reactions given by the vaccinated heifers. The latter may still harbour in their body the non-virulent bacilli incapable of producing lesions, but capable of rendering the body sensitive to the tuberculin. At any rate, all the ten heifers appeared to be in a satisfactory condition of health: they maintained their regular growth. Three of the vaccinated heifers then received a second intravenous injection of 2 mg. of a three-weeks-old culture of bacilli of the eighty-ninth generation in bile-potato medium. Six months later—that is, eighteen months after the commencement of the experiment—all the heifers were tested with tuberculin. On this occasion none of the six vaccinated animals reacted (even though some of them reacted previously), whilst three out of the four controls were manifestly infected. The remaining control seemed to be a case of natural resistance to infection. After a further period of six months two of the vaccinated heifers were again inoculated with attenuated bacilli. The health of the animals remained good. In the spring of 1915, two and a half years after the first vaccination, one of the treated heifers died through an accident; it had been vaccinated three times; autopsy revealed not the slightest trace of tuberculosis, nor did the injection of the triturated bronchial glands into guinea-pigs produce any lesions.

A tuberculin test made in the thirty-second month provoked no response in the two heifers which had been thrice vaccinated, and was quite negative also in another which had been twice vaccinated, whilst two of the three which had only been vaccinated once gave now a positive reaction. In these last the contamination must have occurred between the eighteenth and thirty-second months of infecting cohabitation. Owing to the nature of the German military regulations in Lille, most of the work had to be conducted with great secrecy, and finally the animals had to be slaughtered before the end of the third year was actually reached. Examination of the bodies showed that of the four unvaccinated heifers, three had developed tuberculous lesions and the fourth had proved quite resistant to contamination; two of the three which had been only once vaccinated showed lesions, the third being quite free; the animal which had been vaccinated twice was free from tuberculosis, and the two which had been vaccinated on three occasions showed no signs of the disease.

Calmette and Guérin conclude that the cultivation of bovine tubercle bacilli in successive series on their glycerin-bile-potato medium enables them to obtain a strain of non-tuberculinogenic bacilli perfectly tolerated by cattle and other animals sensitive to the tubercle virus. Their strains have now been going on for thirteen years. This non-virulent race of tubercle bacilli

¹ Calmette and Guérin, *Annales de l'Institut Pasteur*, vol. xxxiv, p. 9, 1920.

acts as a true vaccine in the sense that when inoculated into the veins of cattle it confers on them a resistance not only against experimental inoculation but against contamination by direct cohabitation in infected cowsheds. They believe that this resistance is related to the actual presence of the non-virulent bacilli in the body, and that it does not persist for more than eighteen months as a rule, but that it may be indefinitely prolonged by annual revaccinations. It would of course be desirable that essays of this kind should be carried out on a much larger number of animals and over a number of years corresponding to the average duration of the life of cattle in order that more precise details of the actual value of the vaccination may be obtained.

It is interesting to learn that this living bovine vaccine is inoffensive for man, even by intravenous inoculation in doses of at least 44,000 bacilli. Professor Calmette, in a recent interview with *Le Petit Journal*, while deprecating any too sanguine expectations, expressed the opinion that the results of the experiments opened great possibilities for the future, it was proposed, he added, to make experiments with anthropoid apes, and in order that they might be conducted under the best conditions it would be necessary to have a suitable climate. This, it was believed, had been found in the islands of the Los archipelago, on the coast of French Guinea, West Africa. It is proposed to build a large experimental laboratory on one of these islands, and the Government of West Africa has placed the sum of 350,000 francs at the disposal of the laboratory, it is hoped that when the importance of the experiment is realized the public will subscribe liberally.

FATIGUE AND EFFICIENCY.

THE relation of hours of labour and methods of work to industrial efficiency and to the health and contentment of the workers is being widely studied, both by individual workers, such as Dr. C. S. Myers, and by investigators acting on behalf of the Industrial Fatigue Research Board. The series of reports published by the Board and noticed from time to time in our columns not only contain material of medical importance, but they show that careful systematic investigation of different industries by impartial men of science (who need not have special knowledge of the industry under examination) can bring to light errors in method or in administration which, if undisclosed and unsuspected, may injuriously affect the whole industry and breed discontent among the workpeople. The report on "Fatigue and Efficiency in the Iron and Steel Industry," by Dr. H. M. Vernon, is the latest of this series, and is a definite addition to the growing mass of information on the subject. The difficulty is to find a trustworthy index of fatigue. At present output, although it is affected by many other factors, forms the most convenient quantitative measure of the fatigue induced in an industrial worker by the pursuit of his calling. It may be impossible to devise a better test of the immediate effects of fatigue, but the more remote effects are sometimes suggested in an impressive manner by sickness and mortality records.

The fatigue may be muscular and relate to most of the body muscles, as in the blast-furnace barrowmen in the industry now reported upon, or it may relate to only a few small muscles, as is most strikingly evidenced in ergograph experiments. On the other hand,

it may be chiefly mental, as in some enginemen and crane-men who are seated all day, but who have to be for ever on the alert in order that they may manipulate their levers correctly. Or, again, it may be due to the trying effects of exposure to hot and moist air, as in certain textile processes. Another difficulty arises from the intermittency of many types of labour—for instance, the open hearth steel-melters. On one shift they may have practically no work at all to do, and on the next shift they may have a long bout of excessively hot and heavy fettling. For these and other reasons it will always be a matter of extreme difficulty to compare quantitatively the fatigue induced by various types of manual labour. Nevertheless, it is of interest and importance to compare these types one with another, so far as may be found possible, and group various industries and branches of an industry according to the fatigue they usually induce.

The term "fatigue" must be taken in a general sense as implying a diminished capacity for work, whether this diminished capacity is muscular or mental in origin. The final and perhaps the most important test of the fatigue of a man's calling is to be found in the effect it has upon his health and length of life. This effect is likewise extremely difficult to estimate, for health is influenced by many factors, such as the environment in which the worker lives and the conditions under which he spent his childhood. In certain occupations, again, the health is undoubtedly affected by the inhalation of dust and by chemical poisons. Nevertheless, though it may not be possible, in many cases, to trace an excess of sickness or mortality definitely to the influence of fatigue, it is of great importance to estimate and compare the health of men engaged in different occupations. If the health is clearly proved to be below the average, further investigation ought to be undertaken to determine the cause of the disability.

In the investigation now before us, sickness records of about 20,000 steelworkers for six years were tabulated. The figures showed that on an average the men lost 6.5 days each year from all causes. The steel-melters and pitmen lost 23 per cent more time than the average, the puddlers 20 per cent more, the tinplate millmen 12 per cent more, and the rolling millmen 8 per cent more. Almost all these men frequently work at high temperatures, whilst the engine and crane men and the other workers (chiefly labourers), who work as a rule at ordinary temperatures and on less heavy jobs, showed 8 or 9 per cent less sickness than the average. The excess of sickness among the puddlers was due entirely to rheumatism and respiratory diseases, this, it is thought, may be attributed in part at least to their custom of alternating periods of heavy work with periods of rest or of light work, for the tinplate millmen, who work almost continuously, showed no excess of sickness from these causes. Records of 1,000 blast furnace men, tabulated for a six year period, showed that the younger men lost one to two days more each year from sickness than the steel-workers, while the older men lost four days more.

In regard to mortality, steelworkers aged 25 to 65 showed a 5 per cent lower death rate than all males (occupied and retired); they showed 102 per cent greater mortality from respiratory diseases, but 28 per cent smaller mortality from tuberculosis (mainly phthisis). The steel-melters had a 20 per cent greater mortality than all males, but the other men working at high temperatures and the engine and crane men had a smaller mortality, the blast furnace men had a much higher mortality than the steel-workers, presumably because of their greater exposure

* Reports of the Industrial Fatigue Research Board. No. 5. Fatigue and Efficiency in the Iron and Steel Industry. London: H. M. Stationery Office, 1920.

to the weather. It is probable that all the records yield too low an estimate of death rate owing to withdrawals of some of the less vigorous men.

In some works there was a strange lack of provision for the comfort of the men; for instance, in one district where there are more than two hundred rainy days a year, men engaged in heavy work in the open had no cover whatever; but on the other hand, the men were sometimes more at fault than the employers, for in work where the workmen's shirts usually became wet through it was the exception for a man to keep a spare shirt. As in other forms of manual labour, output usually varied with the temperature; it was greatest in the winter months, intermediate in the spring and autumn, and least in the summer. Again, in different parts, output was affected by the enormous variations in the efficiency with which human labour was utilized and in the efficiency of the plant in the different works; if all the iron and steel works in the country adopted the most efficient methods, Dr. Vernon considers that they could, on an average, improve their output by something between 50 and 100 per cent. There is little doubt that increased output, as a direct result of the greater comfort and contentment of the workpeople, could be obtained by modifications, sometimes exceedingly slight but with a far-reaching effect, of the existing plant and the methods of work. In other industries the provision of suitable seating accommodation, appropriate foot rests, abolition of stooping, improved arrangement of parts used in the fitting up and turning out of complete articles, improvements in ventilation, lighting, noise, vibration, and temperature, have all been found to increase the efficiency of the work of the operatives. A uniform hour-by-hour yield is neither natural with human beings nor is it desirable; a man regulates his output according to his mental state and his conditions of work; hence a discontented mind inevitably leads to lessened production. Investigation in certain branches of the engineering trade showed that not only was efficiency distinctly greater, but the hourly output was almost always increased when the ten-hour day was reduced to an eight-hour day. Dr. Vernon, however, has found that it takes workpeople several months to settle into the new and shorter hours of labour before output and efficiency begin to improve. These and other kindred lessons are full of significance for those who are seeking to readjust the conditions of industrial employment.

SUSSEX PROVIDENT SCHEME.

THE medical provident scheme for Sussex, details of which are given at p. 129, is of very considerable importance; it seeks to meet two of the difficulties of the present time by the medical profession and by the voluntary hospitals. It is designed, on the one hand, to afford general practitioners all the facilities for their patients which hospitals and other existing medical institutions provide, and, on the other hand, to help the hospitals by providing them with a source of income which, if the scheme is as successful as is hoped, will materially improve their financial position. The Sussex scheme centres round the medical institutions in Brighton and Hove. The starting point seems to have been an announcement by the chief general hospital in Brighton—the Royal Sussex County Hospital—that it would in future require in-patients to contribute, according to their means, to the cost of their maintenance in hospital, and would charge out-patients the cost of their treatment. The question then immediately arose whether it would not be better policy from every

point of view that prospective patients of the hospital should furnish their contribution on a provident basis. The hospitals offer their buildings and organization; the ordinary routine of their work is not materially interfered with, and the institution and conduct of the scheme has not cost them anything; even had the number of members been very small, each hospital would still have benefited to the extent of its share of the fund. The subscription for a single member is £1 a year, and for married people with children under the age of 16 £2 a year, and so on; children over 16 must become single members, paying £1 a year. All insured persons are eligible for membership. People who are not insured persons must be approved by a committee of reference formed by the co-operating hospitals. The income limit it is proposed to fix is £260 for a single person, £400 for married people without children, or for a widow or widower with one child, and £500 for a family. At present subscriptions are annual, the whole amount being paid when the applicant is admitted to membership. This simplifies bookkeeping, but is not convenient to all weekly wage earners; consequently arrangements by which the subscriptions of persons employed at works may be deducted weekly by the employer, as is commonly done in many districts, are in contemplation. The scheme has been very fully considered and approved by the whole medical profession in the district, including the hospital staffs, private general practitioners, insurance practitioners, and the Executive Committee of the Brighton Division of the British Medical Association. Its most striking feature from the point of view of medical policy is that all the facilities for diagnosis, as well as for special treatment, afforded by the hospitals and other medical institutions of the towns, are put at the disposal of the general practitioner for the benefit of the provident members under his care. The detailed article to which reference has been made shows the various facilities for diagnosis and special treatment which will be available to members joining the provident scheme and reproduces also a copy of the rules which will be enforced. Consultations in the hospitals will entail some increased expenditure of time and trouble on the hospital staff, but we are informed that 25 per cent. of the money paid to the hospital will be placed at the disposal of the staff. It will be seen also that arrangements have been made for visits by consultants to the home of a patient unable to leave his bed. In the past a good many consultations have been given at reduced fees among people whose financial circumstances now make them eligible to be members of the provident scheme; it is hoped in future to be able to pay a full fee for each consultation. It is believed that such consultations are likely to become much more frequent, inasmuch as the doctor in attendance will no longer have to consider his patient's pocket in suggesting a second opinion. An office for the receipt of subscriptions and the issue of cards of membership has been opened in Brighton, under the general direction of the consultative committee of the provident scheme. The proportions in which the amount received in subscriptions shall be divided among the medical institutions has been determined, and a portion has been set aside for x-ray services and to pay the fees of visiting consultants. A portion is reserved also to defray the expenses of the office at which the business of the provident scheme is conducted, and for legal and auditing expenses. Any surplus will, in the light of the year's working, be allotted to one or more of the co-operating institutions on the recommendation of the joint meeting of the committee of reference of the hospitals and the consultative committee of the provident scheme. As has been said, the scheme is of great interest to the medical profession and to all concerned to maintain the voluntary hospitals. The possibility of adapting it to even so large an area as London is under consideration by some of the hospitals—among others, we believe, the London Hospital and St. Thomas's.

Whether it could be applied to separate districts of London, or whether London should be treated as a single unit, will require very careful consideration before any attempt is made to put a scheme in force.

THE UNIVERSITY OF LONDON'S PHYSIOLOGICAL LABORATORY.

At its meeting last month the Senate of the University of London decided that the physiological laboratory must be closed at the end of July next unless assurance of adequate support is received from the London County Council or other sources before the end of March. The laboratory was established under the direction of Professor A. D. Waller, F.R.S., in 1902, at the headquarters of the University in the Imperial Institute, South Kensington, the equipment being provided out of a fund of £4,000 provided from private sources. It has since been maintained partly out of university funds and partly by private assistance, with the help, during the last nine years, of an annual grant of £500 from the London County Council. This grant is now to be withdrawn, and the University has no funds out of which to make up the deficit. In deciding to close the laboratory, the Senate appears to be influenced also by the need of finding additional room in its present quarters for general university purposes; this is indicated by a further resolution stating "that should adequate support for the transference and maintenance of the physiological laboratory be forthcoming, the laboratory be continued during the pleasure of the Senate elsewhere than in its present quarters, which shall be vacated not later than the end of July, 1921." Physiologists will agree with Sir E. Sharpey Schafer that the closure of the laboratory would be a serious misfortune. "It is," he says, in a letter to the *Times*, "unique from the fact that, being unattached to any particular medical school or college, it has been untrammelled by the necessity of providing elementary teaching in physiology, and has been able to devote all its energies to research. The success it has obtained in this under the able guidance of the director, Professor A. D. Waller, is universally acknowledged. The originality of Professor Waller's methods and the brilliant results which have been obtained from their application—especially in the difficult subject of electrophysiology—are well known. It would be a real calamity if a sudden stop were put to these activities." It is suggested that the reason why the London County Council has withdrawn its contribution at this time is the expectation that it will shortly have to contribute a large sum toward the cost of building new university headquarters. "It would seem," Sir E. Sharpey Schafer concludes, "a pity to allow an active laboratory to be abolished in order to save £500 a year towards the cost of problematical buildings." "Problematical," perhaps, is not quite the right word, because, we presume, something will have to be done for the University, but no building can be undertaken for some considerable time to come. We can only express the hope that, should the London County Council remain obdurate, public-spirited benefactors, recognizing the importance of the University having at least one research laboratory, will come to the rescue. We may, at any rate, express the expectation that means will be found to carry on the laboratory until the question of the new site for the University is settled.

THE FINE CHEMICAL INDUSTRY.

The Society of Chemical Industry has issued a reprint of a paper on the present position of the fine chemical industry which lately appeared in its *Review*. "Fine chemicals" is a term not always understood, and includes not only dyes but the important groups of laboratory chemicals (that is, analytical reagents and research chemicals), pharmaceutical chemicals, and photographic chemicals. The writer of the paper, Mr. C. A. Hill, pleads for the protection of all the fine chemical industries in this

country, on the ground that they are "key" industries, that in spite of much enterprise they are not as yet fully stabilized, and that the Sankey judgement, which has led to "the swamping of the market with German goods," threatens to defeat the best efforts of the British manufacturer. He looks for an extension to fine chemicals generally of the protection recently granted to the dyes industry—that is to say, prohibition of imports except under a system of licences, such licences to be readily granted when British manufacturers are unable to meet genuine demands for essential products. Mr. Hill, of course, puts forward only one point of view, and dismisses, perhaps too summarily, the advantage of reduced cost of medicinal substances under free importation; he describes such reduction as small, problematical, and temporary. But no doubt he voices the general feeling of the manufacturers of fine chemicals, and at least he will not be challenged when he urges that the expansion of an organic chemical industry is intimately associated with developments in biochemistry and therapeutics.

THE ARMY DENTAL CORPS.

A ROYAL WARRANT dated January 4th, 1921, has just been issued as an Army Order, authorizing the formation of a corps to be entitled the Army Dental Corps. The conditions of service and promotion, the rates of pay and half-pay, and the rates and conditions of retired pay and gratuity, are set out in a schedule attached to the Warrant. The Army Dental Corps will be administered by the Director-General, Army Medical Service. It is a joint service for the Army and the Royal Air Force; the personnel will be required to serve under either force, and will be interchangeable; promotion will be carried out on one general list. Commissions as lieutenants may be given to persons duly qualified under regulations approved by the Army Council. Officers will be eligible for promotion to captain on completion of three and a half years' service in the corps; promotion to major and lieutenant-colonel to fill the establishments laid down will be made by selection from among those qualified for promotion. On the formation of the corps certain appointments will be made in the rank of lieutenant-colonel and major to fill the establishments; the remainder of the appointments will be in the rank of lieutenant, except that captain's rank will be given to those who have served three and a half years or more as temporary dental officers. Service as a temporary dental officer will count towards the three and a half years' service for promotion to captain. The daily rates of pay for officers of the corps are: Lieutenants, £1; captains, £1 5s. to £1 8s. 6d.; majors, £1 13s. to £1 18s.; lieutenant-colonels, £2 7s. 6d., rising to £2 12s. 6d. The rates of retired pay will be the same as for officers of the R.A.M.C. Retirement will be compulsory at the age of 55.

QUACK PSYCHO-ANALYSIS.

It appears that psycho-analysis, hitherto cultivated by a certain number of medical practitioners and trained psychologists, has already become a fashionable craze, and whatsoever of good there may be in it is in peril of meeting the fate that befell hypnotism many years ago. It was seized upon at an early stage by some novelists in search of a new plot; this, perhaps, did not matter much, but it is said that every sort of charlatan, crystal-gazer, palmist, and clairvoyant, is now picking up a smattering of the catchwords of psychology, and in particular of the terminology coined by Freud and his disciples, with the intention of exploiting the popular taste for dabbling in psychology, and of preying upon the neurotic section of the public. The neuropath who has heard and read about the marvels of psycho-analysis may become an easy victim to the advertisements of quack psycho-analysts. According to the *Daily Graphic*, which is doing a public service by its exposures, this kind of quack has sprung up, mushroom-like, of late in London and in other cities and towns. For

a fee varying from half a guinea to ten, twenty, or even fifty guineas, according to the gullibility of the patient, wonderful "cures" are said to be promised. It needs little imagination to see that there must be possibilities of blackmail in this new phase of quackery. The police have been active in suppressing the professional fortune-tellers; it would be tragic if by so doing they have helped to turn such parasites to dangerous practices again, now that their old method of exploiting the credulous has been so parodied as to have been rendered comparatively harmless. Ventilation in the lay press may, however, avert the evil. In the meanwhile the injury to the genuine study and practice of psychological analysis must be considerable.

INSTRUCTION OF MEDICAL STUDENTS IN PHYSICS.

There is little doubt that the medical student finds the early part of his studies the least interesting, and mainly because he fails to see the practical application to his future work of much that he is taught at the outset, and that this applies more to physics than to biology or even chemistry. This drawback, partly inherent in the subject, which is so largely based on mathematics, a science that appeals to a type of mind rare in medical men, can to some extent be overcome by the manner in which the subject is presented by the teacher. It is therefore interesting to hear the experience of Professor Marcel Dufour¹ of the Faculty of Medicine of Algiers, who has taught medical students for a quarter of a century, on the best method of instructing them in medical physics. In the first place he points out that the physics course should be essentially practical, and consist as far as possible of demonstrations; for, with rare exceptions, medical students are attracted only by what they can see and tend to forget everything else; abstract reasoning does not appeal to them, and mathematics repels them. The problems of medical physics are not quite the same as those of ordinary physics; they are more complex; thus the laws of optics require some modifications when applied to the eye, and the methods of estimating arterial blood pressure and of the electrical testing of muscles and nerves differ from those employed by a physicist in taking a record of the pressure of fluid in a reservoir or of the resistance of a copper wire. These differences should be explained, and the instruments of precision employed in clinical practice should be fully explained by the lecturer on medical physics. The importance of pointing out the practical bearing of physics on medical problems is insisted on, and Professor Dufour recommends that the instruction in medical optics should be given in the ophthalmic clinic, and in medical electricity in the electrical and x-ray departments. Lastly, in order to maintain attention and ensure that the students really understand what they are being taught, it is advisable that the demonstrations should be interspersed with questions.

WOMEN ON JURIES.

The daily papers are making frequent references to the service of women on juries. It is pointed out that here "Mr. A. B. objected to all the women jurors," or that there "Mrs. C. D. objected to serving on the jury because she felt nervous." This is the kind of information which must, we suppose, prove attractive to the public, or it would not be given; but in the meantime what is the position? The mixed jury is an accomplished fact. Whether the women summoned to attend are very grateful to those who so strenuously fought for women's rights may be open to question, but so far as can be judged from the experience of quarter sessions, the presence of a few women on the jury makes little or no difference to the administration of justice. One of the chief objections to the service of women in this capacity has been that they must inevitably be called upon to try cases of an unpleasant nature. This is, of course, true; there are

certain types of case, all too common in our criminal courts, to which no women should be forced to listen. But in the ordinary case, say, of indecent assault, it is often necessary to examine and cross-examine a woman upon all the revolting details in the presence of a jury of men. To have a few women on the jury should ease the situation, nor is there anything so very novel in a jury of women. It is stated in a well known book on the criminal law that in England when a woman is convicted and sentenced to death, the clerk of the court, after sentence, is to ask whether the woman has anything to say in stay of execution of the sentence. If she then alleges, or the court then or later has reason to suppose that she is pregnant, a jury of twelve matrons should be empanelled and sworn to try whether or not she is quick with child. "The jury," according to *Archbold's Criminal Pleading*, "may be empanelled forthwith, *de mulieribus circumstantibus*, the judge first ordering that all the doors be shut and that no one be allowed to leave the court." Should the matrons desire the assistance of a medical man, a medical man is requested by the court to retire and examine the prisoner. When his examination is concluded the jury of matrons is recalled into court, and his evidence is given in their presence and that of the prisoner. If they find the person quick with child, the court stays execution of the capital sentence on the offender until she shall be delivered of a child or it is no longer possible in the course of nature that she should be so delivered.

A SITE FOR THE UNIVERSITY OF LONDON.

A new turn has been given to the discussion about the site for the headquarters of the University of London by the suggestion that Holland Park would be suitable. The park is about a mile from the Imperial Institute, where the University's headquarters are now housed; it covers altogether an area of about 60 acres, and about 35 acres would, it is understood, be immediately available. It is not traversed by public roads, so that the area could be laid out as a whole. The site offered by the Government in Bloomsbury contains 11½ acres, but it is cut up by roads into four plots, affording a total building area of about 8½ acres. The present tenant for life of Holland Park, Lady Ilchester, has stated that the much larger area which could immediately be made available there for building would cost much less than the £400,000 mentioned as the price of the Bloomsbury site. The suggestion appears to have the support of the London County Council, since it was put forward by Captain Swinton, a former chairman, and is supported by Colonel Levita, a member of its Education Committee. The Council is concerned in the matter because it is understood to be willing—following the example of the councils of many great provincial cities, such as Birmingham, Liverpool, Manchester and Sheffield—to help the University with money. The London County Council has not disagreed with the proposal to accept the Bloomsbury site, but it is not bound to it. Should the site be accepted by the Senate of the University the London County Council has undertaken to contribute not more than one-third of the contribution made by the Government in respect of expenditure not exceeding one million. Technically the decision as to the site rests with the Senate of the University, but obviously, as it has no large funds for building, it must be influenced by the action of the London County Council, as well as that of the Government. The Government has so far definitely refused to contribute to the cost of building. It seems very desirable that both the Senate and the London County Council should reconsider the position in view of the suggestion to acquire Holland Park or some part of it. That site is a good deal further west, and no doubt the centre of London has during the last hundred years ceased to move west, but a roomy site would go far to compensate for any disadvantages of this nature. As has been said,

¹ M. Dufour: *Rev. générale des sciences pures et appliquées*. Paris, 1920, xxxi, 787.

Holland Park is only about a mile west of the present headquarters of the University, of the Natural History department of the British Museum, and of the Imperial College, though that great institution does not at present wish to become part of the University.

THE PRINCE OF WALES.

THE PRINCE OF WALES, who was elected an honorary Fellow of the Royal College of Surgeons of England last July, will attend the Hunterian Festival dinner on February 14th and receive the diploma of honorary fellowship from the President, Sir Anthony Bowlby. In becoming an honorary Fellow of the College the Prince of Wales follows in the footsteps of his grandfather and father. King Edward VII when Prince of Wales was elected an honorary Fellow in June, 1900, and admitted in the following month, shortly before the centenary celebrations, which he attended. King George V, when Prince of Wales, was elected an honorary Fellow in February, 1909. The Duke of Connaught, who is now in India, was elected an honorary Fellow on the same day, July 24th, 1919, as the present Prince of Wales. The only other surviving honorary Fellow who does not belong to the medical profession is the Earl of Rosebery, who was admitted in 1900. There have been two other such honorary Fellows—namely, the Marquis of Salisbury, who was Prime Minister at the time the centenary was celebrated, and Field-Marshal Earl Roberts, who was elected in 1901.

THE TRANSFER OF SANATORIUM BENEFIT.

It will come as a surprise to many persons to learn that the Scottish public health authorities have been able to take over the provision and administration of sanatorium benefit in their areas from January 1st, seeing that Dr. Addison has found it necessary to postpone until May 1st the transfer of similar provisions from the English and Welsh Insurance Committees to the English and Welsh County Councils. The official communication issued by the Scottish Board of Health, which is given on page 23 of the SUPPLEMENT this week, states exactly what is occurring, but does not explain the difference in the circumstances which enables that body to go forward while the English Ministry of Health has to delay action for a period of four months. It appears that in its former capacity as the Scottish Local Government Board the Scottish Board of Health obtained, under an Act of Parliament passed years before the Insurance Act came into being, powers to secure the notification of tuberculosis, and to sanction the provision of sanatoriums by local authorities. When the National Insurance scheme was set up these powers were curtailed in order that they should be exercised for insured persons by the Insurance Committees. Last June, when the Public Health Amending Act was placed on the statute book, it was laid down for the United Kingdom that the Insurance Committees should not continue to deal with sanatorium benefit, but that the work should be undertaken by county councils. As regards Great Britain and Wales, however, the Act made further legislation necessary in order to enable county councils to fulfil this duty. Dr. Addison expected to be able to complete the transfer by means of the Tuberculosis Bill, but owing to the pressure of other Government business that measure had to be abandoned for the session, and with it the intention of effecting the change on January 1st. In the autumn, having no reason then to anticipate difficulty, he had informed the authorities in England and Wales of the proposed change, and the Scottish Ministry of Health did the same. But as the legislative authority for giving the new powers to English and Welsh county councils was not obtained he had to notify the English and Welsh authorities that action would be postponed until May 1st, 1921, by which date a Tuberculosis Bill would become law. The Scottish Board

of Health not being in this difficulty decided to let the notification stand, and that is how it happens that the Scottish health authorities have already taken over the arrangements for sanatorium benefit in Scotland.

HOSPITAL INQUIRY COMMITTEE.

WE are now able to confirm the statement made in our last issue that Viscount Cave would be chairman of the committee appointed by the Minister of Health with the following terms of reference: "To consider the present financial position of the voluntary hospitals and to make recommendations as to any action which should be taken to assist them." Sir Clarendon Hyde, Mr. R. C. Norman, and Mr. Vernon Hartshorn have also been appointed members. A representative for Scotland will be added, and it is proposed also to include a chartered accountant of high standing. The secretary of the committee is Mr. L. G. Brock, C.B., Assistant Secretary in the Ministry of Health, to whom all communications should be addressed at the Ministry of Health, Whitehall, London, S.W.

THE KING has approved the appointment of Mr. S. P. Vivian, a Principal Assistant Secretary in the Ministry of Health and Deputy Registrar-General, to be Registrar-General in succession to Sir Bernard Mallet, K.C.B.

At a special meeting of the governors of the Royal Chest Hospital held at the Mansion House on January 17th, it was resolved, as foreshadowed in our last issue at p. 96, to extinguish that institution as a separate entity, and to merge its special work in that of the Great Northern Central Hospital.

Scotland.

THE Secretary for Scotland has appointed Dr. G. H. R. Gibson, D.S.O., Croix de Guerre, to be Deputy Commissioner of the General Board of Control in Scotland.

ORTHOPAEDIC TEACHING IN EDINBURGH.

A proposal is under consideration in the University of Edinburgh for the establishment of a department of orthopaedics, and Sir Robert Jones devoted his Cameron lecture, delivered before the university on January 14th, to a consideration of the necessity of orthopaedics and its relation to the prevention and cure of deformity. The chair was taken by Professor Lorrain Smith, Dean of the Faculty of Medicine, and the large anatomy lecture theatre was crowded. The Cameron prize was founded in 1878 by the late Dr. Andrew Robertson Cameron, of Richmond, New South Wales, and the income, which, after defraying expenses, amounts to £150, may be awarded annually to a person who in the course of the five years immediately preceding has made any highly important and valuable addition to practical therapeutics. The first award under the present regulations was made in 1898, when M. Pasteur was the recipient. In the following years it was awarded to Lord Lister, Sir David Ferrier, Sir Victor Horsley, Professor Behring, Sir William Macewen, Sir Thomas R. Fraser, Dr. S. Monckton Copeman, Sir David Bruce, Mr. W. Haffkine, Sir Patrick Manson, Sir Ronald Ross, Professor Finsen, Professor August Bier, Dr. Simon Flexner, and Professor Paul Ehrlich. The last award was made in 1915 to Sir Lauder Brunton, in recognition of his researches in pharmacology and their application to therapeutics. The Chairman said that Sir Robert Jones had decided to present the amount awarded to him as a prize for orthopaedics in the University of Edinburgh. After the delivery of the lecture, which will be published shortly in full, a vote of thanks to Sir Robert Jones was moved by Sir Harold Stiles, professor of clinical surgery in the university, who expressed the hope that before long there would be established in that great imperial university a department of orthopaedics worthy of it.

NEW REGISTRAR-GENERAL FOR SCOTLAND.

Dr. James Craufurd Dunlop, F.R.C.P.Ed., Superintendent of Statistics in the Registrar-General's Department, Edinburgh, has been appointed by the Secretary of Scotland to the post of Registrar-General for births, deaths and marriages in Scotland. In addition to his many years' service in the General Register House, Dr. Dunlop has been Inspector under the Inebriates Act for Scotland and assistant adviser on the Prison Commission for Scotland. He was a member of the Royal Commission on the Care and Control of the Feeble-minded. In his official capacity he was closely concerned with the taking of the last census in 1911.

India.

SUBASSISTANT SURGEONS.

THE fifteenth All-India Subassistant Surgeons' Conference was held in Delhi in December, 1920. The Chairman of the Reception Committee gave an account of the grievances under which the subassistant surgeons labour, laying special stress on the low pay, the increase of the medical course to five years, and the failure of the Lovett Committee to meet the desires of the service. The Director-General I.M.S. was elected Chairman of the Conference, and in a short opening address expressed his full sympathy with the aspirations of the subassistant surgeons. The value of their work, he said, was fully recognized by the Government of India. He said that in his view a five years' course of education was desirable. At present, subassistant surgeons filled many posts which the provinces could not afford to fill with assistant surgeons or subassistant surgeons who had taken out a five years' curriculum. This, so far as he knew, was the only excuse for having two grades of qualified men in India. While it was not possible to prophesy what would happen under the reforms scheme, he thought it certain that the class of medical men willing to accept a small salary would continue to be in demand for the smaller dispensaries. With regard to pay, he reminded his hearers that it had been improved during the war, and added that a further increase was under consideration. More doctors were wanted in India, but the need was in the country districts and not in the towns, where there were too many. Country dwellers were too poor to pay fees, and the provincial governments therefore maintained dispensaries; there was generally no difficulty in finding applicants for the medical posts. Afterwards the Viceroy opened the exhibition of sanitary and scientific appliances and indigenous drugs. In doing so, he referred particularly to the infant welfare section of the exhibition, and spoke in high praise of the excellent work unobtrusively done by the subassistant surgeons.

A DENTAL SCHOOL IN BOMBAY.

The Government of Bombay have submitted proposals for the establishment of a dental school and infirmary in Bombay, and inquiries are proceeding on the Continent and in America as to the best means of making a start. Meanwhile teachers in dentistry have been appointed in the Grant Medical College and three medical schools in the Presidency. When the dental school becomes established, the College of Physicians and Surgeons of Bombay will institute a registrable qualification in dentistry.

CENTRAL BOARD OF HEALTH.

A medical conference held in Simla in May, 1919, recommended the creation of a Central Imperial Board of Health for India, the appointment of a Director of Medical Research, and the establishment of an epidemiological statistical office. The Government of India decided to act upon these recommendations, and the plan, having received the sanction of the Secretary of State, will shortly come into force. The epidemiological office will be under the direction of the epidemiological statistician, who will be assisted by a body of expert statisticians. The Central Board will advise the Government of India and local governments on hygienic matters. The duty of the director of medical research will be to co-ordinate the work carried on by the Research Fund Association and the research work undertaken by the Government of India directly.

Correspondence.

RESUSCITATION OF THE APPARENTLY DEAD
AND THE RELATION OF CARDIAC
INNERVATION TO IT.

SIR,—The series of papers and notes which have recently appeared in the *BRITISH MEDICAL JOURNAL* on the resuscitation of the apparently dead have not only a practical but also a scientific interest. No situation with which the practitioner can be faced calls for more calm and prompt action than the sudden and unexpected cardiac failure with which he has at times to deal. Arising as this condition does, occasionally, under apparently trivial provocation, there is also no situation which may be more important for patient and practitioner alike. The patient may tragically lose his life and the practitioner be placed in a very unenviable position, which, in the event of a fatal issue, may require all his philosophy, and the intelligence and charity of his neighbours, to face with composure.

More than thirty years ago, when a general practitioner in the north of London, I was asked to visit a man who was about 40 years of age, but too grizzled for his years, and who had been suffering for ten days from tonsillitis. He had taken little food and had had no medical attendance. His wife, who alone nursed him, was far advanced in pregnancy. On examination I found he had some pus in one of his tonsils, and asked him to sit on the edge of his bed while I punctured the gland. On the first touch of the lancet he fell back on his bed apparently dead. Pulse and respiration ceased and the pupils became widely dilated and motionless, as one always observes at the moment of death. I believed him to be dead and thought there was little prospect of reviving him. I conducted his wife out of the room to another part of the house, fearing the effect upon her in her condition, of the discovery of her husband's sudden death, and asked her to remain there till I returned.

On going back to the patient I found him in the condition in which I had left him—motionless, breathless, pulseless, with the same dilated and fixed pupils—in short, apparently dead. After artificial respiration for a time, with firm expiratory compression of the thorax, a single natural respiration occurred, and later another and yet another, until respiration and circulation were restored. I made him comfortable in bed, announced his satisfactory condition to his wife, who returned with me to the bedroom, and neither he, who lived for many years afterwards, nor she, was ever aware of the *mauvaise quarte d'heure* I had spent with the apparent corpse.

The ailment in this case was comparatively trifling; the patient was exhausted by voluntary abstention from food, and the pricked tonsil sufficed to induce a cardiac still-stand. Shock arising in any quarter may, under such circumstances, induce a profound cardiac inhibition or failure, but the tonsils, palatine and pharyngeal, from the special innervation of these parts (vago-glosso-pharyngeal), probably render them more intimately related to the heart and more easily provocative of such an accident as I have described. Indeed, it is probable that some disasters in the removal of tonsils and adenoids ascribed to the so-called status lymphaticus are really due to neural inhibition of the dragged heart. Laborde's method for the resuscitation of the apparently dead by tongue traction, which has been successfully used both in the newly born and in other conditions, points to this cardio-pharyngeal nerve relation as important under these circumstances.

The case I have mentioned resembles in a measure the third quoted by Dr. Craunston Walker (p. 47). While I do not agree with him that the nature of the syncopal attack can properly be termed a Stokes-Adams seizure, for the ventricle is innervated independently of the excitatory system and may be inhibited by vagal pressure when the auricles fail to be so, the result of artificial respiration was, in his case, also favourable.

A distinction must be drawn between the sudden onset of apparent death in those who are under the influence of an anaesthetic and in those who are not. The reflexes of the latter are, naturally, more sensitive than those of the former. It is the anaesthetized who will most frequently require laparotomy and cardiac massage when the heart fails, and, fortunately, under these circumstances, you've got the man, you've got the knife, and you've got the adrenalin too. As Mr. Fisher states (*BRITISH MEDICAL JOURNAL*, November 6th, 1920, p. 693), the laparotomy necessary to allow cardiac massage is an easier operation than tracheotomy, which all practitioners are assumed to be capable of performing. It must be remembered, however, that many cases of cardiac failure under an anaes-

thetic may be resuscitated by artificial respiration, to which, I think, tongue traction should be added more frequently than it is. Experience, however, suggests that one should, even in trivial procedures such as those I have mentioned, be prepared with some local anaesthetic and the adrenalin syringe in case of accident. Mr. Fisher's article has both practical and theoretical interest, and the same may be said of Professor Gunn's contribution (*British Medical Journal*, January 1st, p. 9). Both these gentlemen and Dr. Walker refer to the relation of the cardiac nervous system to the conditions they deal with and to the means they employ in its treatment, while Professor Gunn has experimentally shown and explained the value, not only of adrenalin, but also of atropine, under the circumstances in question.

It is within quite recent memory that such emphasizing of the cardiac innervation was out of vogue, and that those who dwelt on its importance in cardiac action were considered as merely exposing their own archaicism. Even now there are those who only concede some modification of their purely myogenic conceptions with reluctance. It is, however, the case that to day most writers describe the excitatory system as "neuro-muscular," and even the pacemaker, as I have shown (*Journal of Anatomy and Physiology*, July, 1912), is abundantly innervated, and therefore under nerve control.

The future also holds some modification of prevalent notions of the sensory element in cardiac neurology. When the conditions and circumstances in which sensibility in the autonomic system manifests itself are better understood, we may expect a change in conceptions of the nature and expression of visceral pain, including angina pectoris, at present entertained by some "authorities." Cannon and Washburn's demonstration (*American Journal of Physiology*, vol. xxix, p. 441) of the relation of hunger pains to gastric contraction is a useful contribution in this direction.—I am, etc.,

London, W, Jan 12th. ALEXANDER BLACKHALL MOPSON.

ADRENALIN IN RESUSCITATION.

Sir,—In your issue of January 8th Dr. Cranston Walker raises a point of great therapeutic importance. Some years ago, in a desperate case of heart failure during chloroform anaesthesia, when my assistant was about to inject strychnine hypodermically into the precordium, the idea suddenly struck me to plunge the needle directly into the heart apex. Since then I have adopted this plan on at least six or eight occasions, and, like Dr. Cranston Walker, I have had varying results. All except two of the cases occurred in France, whereof I have no records.

A few weeks ago Dr. D. H. Fraser anaesthetized a boy of 11 with ethyl chloride, in order that I might remove his tonsils with the reversed guillotine. Apparently all went well, as regards both the anaesthetic and operation. But immediately following the latter, and less than a minute after its commencement, heart beat and respiration ceased (I am unable to say which failed first). All the ordinary means of resuscitation proved useless, the boy was seemingly dead. At my request Dr. Fraser gave 5 minims of liquor strychninae directly into the heart muscle. In a quarter of a minute or less the heart beat, and almost immediately the respirations recommenced. On regaining consciousness the patient complained of most violent and distressing precordial pain. It was surmised that the needle might have punctured a large branch of a coronary vessel, but there were no signs of haemopericardium. The spasms of pain passed off gradually, and next day he was well.

In his commentary on his third case Dr. Cranston Walker, with great fairness, points out that had adrenalin been available a little sooner it would have received underved credit for a resuscitation which actually occurred without the intervention of the drug. I would like to go further—and this is my point in the present letter—and say that, at any rate when using strychnine in my cases, it is debatable whether the drug has played any part. On each of the several occasions I have remarked in the theatre that the stimulus was probably mechanical—the prick of the needle rather than the action of the drug. This view may find support in the case above referred to, in which the persistence of anginal pain for several hours without physical signs suggested that the heart had received a deep and brisk prick. In the absence of proof

it is well to give the drug the benefit of the doubt; and since, on physiological grounds, adrenalin may be more effective than strychnine, I shall, since reading Dr. Cranston Walker's interesting article, use adrenalin on any future occasion.—I am, etc.,

London, W, Jan 11th.

H. LAWSON WHALE.

Sir,—In connexion with the use of adrenin preparations for reviving the heart, the possibility of an overdose should be borne in mind. Adrenin exerts a depressor as well as an augmentor action on the heart, but when employed in small concentrations the depressor action is negligible. I have, however, observed that depressor action at a concentration of 1 in 250,000, and found it greater in hearts that were beating feebly than in hearts beating strongly. Hence I would suggest that a concentration, as suggested by Mr. Lockhart Mummery, of 1 in 50,000 might be too great; 1 in 500,000 would be as effective and safer.

I have also found that the stimulating action of adrenin outlasts its actual presence in the medium by which it is conveyed to the heart, and that this property can be utilized experimentally to obtain augmentation only. A drop of adrenin is placed in the perfusing fluid and simply washed through the heart. Such conditions might be paralleled by injecting adrenin into the heart cavity and then expelling it by massage. The depressor action would accompany the adrenin, but the augmenting action would remain.—I am, etc.,

W. BURRIDGE, M.B.

The Physiological Laboratory, University of London,
South Kensington, Jan 15th.

Sir,—Few clinicians appear to know that acupuncture of any part of the cardiac muscle—the right auricle having been proved to be the most excitable region in man—produces powerful cardiac contractions. How, then, are we to decide whether the adrenalin or the acupuncture was the remedial agent in Dr. Cranston Walker's cases? In all cases in which cardiac massage is contemplated we ought first to try simple acupuncture of the muscle of the right auricle.—I am, etc.,

London, N W, Jan 12th

LEONARD J. KIDD.

THE VOLUNTARY PRINCIPLE AND THE BRADFORD BOGEY.

Sir,—Your issue of January 15th has a letter from Mr. J. Basil Hall, of Bradford, on the voluntary principle of hospitals, which is so little helpful towards the elucidation of a difficult problem, that I should not have troubled to reply to it, but that its pointed references to myself might make some of your readers think that I ought to answer it. If, also, I refrained from doing so, as on first reading it was my intention, it might appear that it seriously invalidated the position I took up at the recent conference of staffs of voluntary hospitals, that the voluntary principle was becoming, if it had not already become, obsolete.

In the last paragraph of Mr. Hall's letter—about one-seventh of the whole letter—is contained a contribution to the subject which may be of value. The bulk of the rest of his letter is concerned with my own shortcomings, and in it Mr. Hall seems to have had in mind the advice of a famous barrister "When you have a bad case, abuse the plaintiff's attorney." I use the word "abuse" in a technical sense only, as I do not wish to imply that Mr. Hall has transgressed the limits of courteous controversy in any way.

Mr. Hall starts by the somewhat bold assertion that "nearly everything that has been said about Bradford up to the present time is more or less untrue." I have no means of knowing "nearly everything that has been said about Bradford," to claim such knowledge would be to make a claim to omniscience, which I personally would not wish to make, and which I doubt if Mr. Hall himself means to make. I suspect that what Mr. Hall means is that some of what has been written about the Bradford hospitals is inaccurate, and this can be readily granted. In fact, Mr. Hall proceeds to demonstrate the truth of this to the maximum amount possible in the comparatively short space of most of the rest of his letter.

He states that it is untrue "that no poor patient can get admission to the Royal Infirmary unless he pays a fee to a member of the honorary staff," and he then proceeds to say that "it appears that Dr. Peter Macdonald of York repeated the Bradford story . . . a story which is just so much propaganda to promote a general socialistic hospital policy throughout the kingdom." Mr. Hall is mistaken. I made no such statement and I repeated no such statement. I was aware of the statement and I did not credit it.

Mr. Hall then proceeds to traverse my illustration from the Bradford case, of the inadequacy of hospital supply by voluntarism. I said that Bradford voluntary hospitals had 361 beds and supplied a population "which cannot be less than half a million." Mr. Hall says the Bradford population is something nearly approaching 300,000. What has this got to do with it? The estimated population of Bradford is, for 1920, 295,636. The population of greater Bradford, if the projected extension of the municipal boundary goes through, will be 374,943; and the original proposals for extension would have made it about 420,000. But does Mr. Hall mean to imply that no patients come to the Bradford hospitals from outside the city boundaries, or any proposed city boundaries? Whatever Mr. Hall's capabilities as a controversialist may be, I know that his professional skill is such that he attracts a clientele of patients from far outside the city boundary, and so do his colleagues; and one of the Bradford voluntary hospitals is the Eye and Ear Hospital, and its clientele is drawn from a population which I am convinced is nearer a million than half a million.

The radius of twenty-miles round the city of Bradford, in which Mr. Hall says that there are a score of hospitals, contains a population of at least two millions. I adhere to my estimate of half a million, and I believe it is not far wrong.

But what if it were? Does Mr. Hall consider 361 beds as providing adequate hospital accommodation for a population of 300,000, with the increasing appreciation by people of all classes of life that hospitals and nursing homes are the right places to treat illness, and that houses built to live in are not the best places to be ill in? Mr. Hall's words give the impression that he means this; but he surely does himself an injustice.

Mr. Hall proceeds to denounce the character of the buildings of the Bradford Municipal Hospital. I do not know these well. My knowledge of them is derived from a hurried visit, and they were evidently not ideal; but all circumstances have to be considered—among these circumstances the present difficulty and cost of building—and, having regard to these circumstances, I only wish that we had the Bradford Municipal Hospital at York.

Next we are told by Mr. Hall that there is "no waiting list at the Bradford Royal Infirmary"—with an exception of no importance. I accept Mr. Hall's statement, but I confess to its putting a strain upon me: the difference from most other voluntary hospitals is so great, and I wonder how recent it is that this condition of affairs has been brought about. I have a sort of recollection that the size of its waiting list has at times been urged in the past by the authorities of the Bradford Royal Infirmary as an argument for its extension; but in this my memory may misserve me. Is the explanation that the Municipal Hospital has absorbed the voluntary hospital's waiting list?

Finally, Mr. Hall would complete my discomfiture by a mass of statistics. "Things to handle, to have on one occasion talked of 'inaccuracies, incredible inaccuracies, and statistics.' A variant of the story substitutes for 'statistics' 'medical evidence.' Either would do in this case. Mr. Hall is no statistician. What in the name of all that is wonderful is the good of quoting 1914 figures in this year 1921? A whole epoch has passed since 1914. In 1914 I had a bank account, which was sometimes not overdrawn. I could draw from it nice clean golden sovereigns. With each sovereign I could buy about 100 lb. of sugar, or 60 loaves, or 20 lb. of butter. Five or six would buy me a suit of the finest stuff from Bradford's wonderful mills. Nothing of this remains in 1921. I wish it were 1914 to-day, and so do a good many more, non-socialists as well as socialists.

But the reason why I am supposed to have been "talking

through my hat," whatever that may mean, is that I am supposed to have stated that the "Bradford Royal Infirmary is bankrupt to the tune of £1,000 a month." I made no such statement. What I did state was that the chairman of the Bradford Royal Infirmary was reported to have made this statement. I have a copy of the *Yorkshire Observer* of December 4th by my side as I write. In Mr. George Priestman is reported to have said, at the opening of a bazaar at the Royal Infirmary, that "to do the expenditure (of the infirmary) was at least £41,000 . . . and he did not think that in the current year more than £30,000 would be raised" (as income). I believe Mr. Priestman to be the chairman of the Board of the Bradford Royal Infirmary. Is not, then, Mr. Hall's quarrel with the chairman? Ought not he to turn the battery of statistics on to him; or would it not be better for Mr. Hall to avoid statistics like the plague, and to confine himself to things that are within his capacity? Enough said about Mr. Hall's statistics.

I do not care also for his advice. He quotes with approval as a rule of conduct the adage: "Never believe anything you hear and only half what you see." So far from endeavouring to base my life on this very naïf principle, I always regarded it as evidencing a rather despicable outlook on life which I should endeavour to avoid; but I must say that if I were to read many letters like Mr. Hall's, I would have to confess that it might be wiser for me to reconsider my methods.

So much for six sevenths of Mr. Hall's letter, which concerns myself, and in which he is mostly wrong. I shall endeavour to forget it. It merely serves—or, had it been in any way effective, would have served—to darken counsel and to shut out light. But I shall remember the last seventh of his letter, in which he makes a contribution to the problem of voluntarism which may be of value. The proposal he there makes is, new to me. It is worth exploring as a means of reconciling the old and dying system of voluntarism with the modern view of civil responsibility. I personally would welcome "co-operation" as heartily as Mr. Hall, although I doubt if the co-operation is to be worth much if it is to be between an inferior indeed second-rate, municipal hospital and a superior voluntary one, which is to be first class, as Mr. Hall suggests. No municipality could consent to this, nor could the staff of the municipal hospital.—I am, etc.,

York, Jan. 15th.

PETER MACDONALD.

PERSISTENCE OF THE DUCTUS ARTERIOSUS.

Sir,—Dr. Wilson Hall's interesting comments (page 8) on my paper (briefly noticed in your issue of December 25th, 1920) raise two distinct questions:

1. Is the characteristic bruit heard more often in those patients who survive to adult life than in infants? This question was asked in the discussion at the meeting of the Bristol Medico-Chirurgical Society to which my paper was read, but in a rather different form—"How is it that we do not hear this bruit in the newborn infant, considering that the ductus arteriosus normally remains pervious for a few days after birth?" It is interesting to learn from Dr. Wilson Hall's cases that even in those children whose cyanosis is presumably due to an abnormally long persistence of the ductus this murmur was not heard. Possibly the increased force of the adult blood current has something to do with this discrepancy.

2. Is the bruit heard only in those patients to whose congenital anomaly an acquired endocarditis has been added? The case I recorded in which this infection was superimposed on the vascular deformity was one of a young woman whose murmur had existed for at least ten years under my own observation before the symptoms of ulcerative endocarditis arose. Further, cases have been recorded (such, for example, as that published by Dr. George A. Gibson in the *Edinburgh Medical Journal*, 1900, new series, vol. viii, p. 1), in which the murmur observed during life has been identified after death with a persistency of the ductus arteriosus to which no endocardial infection has been added. The bruit is, therefore, due to the anomaly itself, and not to any endocarditis that may have supervened.—I am, etc.,

CAREY F. COOMES, M.D., F.R.C.P. Lond.

Clifton, Bristol, Jan. 16th.

THE PREVENTION OF VENEREAL DISEASE.

SIR,—I regret that depreciation of others should form the bulk of Sir Bryan Donkin's letter in your issue of January 15th, for, after all, medical women have, like others, a definite duty to the State in regard to the combating of venereal disease, and, if a determination exists in the minds of many of them to go carefully and with clean hands into this complicated subject, surely the community stands to gain thereby.

The Medical Women's Federation was formed four years ago, with the full knowledge of the British Medical Association, towards which it stands in much the same relationship as does the Society of Medical Officers of Health. Our membership is over 600 and is steadily increasing; it includes all the leading medical women of Great Britain, and these we hope are also members of the British Medical Association. Twice a year a council sits for two days, being attended by representatives from all quarters of Great Britain, and this council acts by appointing representatives on the various committees of the British Medical Association and in other ways, as the official body for obtaining and collating the opinion of medical women—an opinion periodically asked for by Government and by others—and heretofore asked for in vain.

Since women by instinct think in terms of the rising generation, it is inevitable that many medical women who are married, as also their colleagues who are engaged in inspecting children or in conducting pre-natal or venereal clinics, or occupied by hospital or private practice, should desire to bring their scientific and practical experience to bear on the venereal problem. So strongly was this felt at the annual meeting of the Medical Women's Federation in 1918—attended by 100 to 150 members—that it was decided then and there to appoint a committee of those specializing in venereal disease, or specially interested in the subject, with a view to both studying the facts and helping in the national emergency.

Obviously the effective way of helping in this matter, upon which medical men differ so widely, has required much thought. On the one hand stands the Society for the Prevention of Venereal Disease insisting that personal self-disinfection provides the royal road to a marked lessening of venereal disease, whilst on the other side are found men of marked ability and administrative experience—as, for example, Dr. Robertson, M.O.H. Birmingham, who is satisfied that it is impossible to rely on the scientific and successful application of methods of self-disinfection to the civilian community, and is further positive that its propaganda will tend to wreck the home life of our country.

On behalf of the Medical Women's Federation I beg absolutely to deny that there has been "deliberate misrepresentation" of the principles and practice of the Society for the Prevention of Venereal Disease. Herewith are the facts. That society issued a leaflet entitled *Directions to Women*. One of our committee wrote to Dr. Winney Hay on the matter, and his reply gave not the slightest indication that the leaflet was meant for prostitutes only. Moreover, the words of their president, to the effect that his society was going "to take every step to ensure that all boys and girls, men and women in the United Kingdom shall have access to the latest scientific knowledge with regard to immediate self-disinfection," lead us to believe that the "directions" were meant to be general. Inasmuch as our short protest has had the desirable result of inducing the Society for the Prevention of Venereal Disease hastily to state that this obnoxious leaflet called "Directions to Women" should in reality be titled "Directions to Prostitutes," I consider that we deserve the thanks of the public. No man now will be justified in handing one to his wife, as the title suggests, although I gravely fear that what is considered good printed advice for one sort of woman may soon be judged as desirable, even for a loyal wife. Consequently, however many explanations are forthcoming, so long as the leaflets are in evidence our desire to criticize them will persist.—I am etc.,

MARY D. STURGE,

President Medical Women's Federation

Birmingham Jan 1921

SIR,—A year ago Dr. Otto May and other members of the National Council for Combating Venereal Diseases expressed in letters to the *British Medical Journal* concern as to the effects on sexual morality which might

result if people who were liable to incur danger from venereal disease were taught to disinfect themselves quickly. It was feared that such people, hitherto restrained by a sense of communal disapproval, might suppose a communal sanction. Dr. May also expressed doubts as to the efficacy of quick disinfection and desired that the Portsmouth results, and especially those published by me, should be submitted to actual examination. He was told how the Portsmouth figures could be easily and exactly tested—and was challenged to test them—and thereupon relapsed into a silence unbroken even by apology. To day Dr. May, still concerned about morality, is still arguing, on grounds of the prevalence of venereal disease among British troops in Germany, that quick disinfection is ineffectual. Let us, then, get to the facts again. They should greatly interest the mass of the profession—the panel doctors who are collecting materials for the ingenious statisticians of the Ministry of Health.

Before, during, and after the war many medical officers in charge of troops had reduced venereal disease among them from high figures almost to the vanishing point (see the *British Medical Journal*, January 24th, 1920). All these results, which can be fully tested from independent official sources, were achieved not by the issue of packets, but merely by giving men clear and simple instructions as to the mode and danger of infection and the necessity and method of disinfection. Ample disinfectants for supplying men who ask for them have been present since Lister's time in every medical inspection room. In 1918 the War Office resolved to apply the method of quick disinfection to the whole army. An "expert" was placed in charge of the arrangements. Delay occurred, and it was then discovered that millions of "packets" were being manufactured. Unavailing protests that not packets, but clear instructions were required, were made. Delay gave "influential people" then opportunity. The officials, or the expert, proved plastic. When the packets arrived it was intimated that they were for 'early treatment.' Early treatment is, of course, another name for disinfection, but delayed, not quick disinfection. Presumably it was hoped thereby to delude soldiers into the belief that they were curing not preventing disease. Unavailing protests were again made, and it was predicted that, lacking instructions, the supply of unnecessary packets would not reduce disease. The expected and the predicted happened. Venereal disease was not reduced in the army at large, but in the Portsmouth "area"—all Hampshire and Dorsetshire except Southampton, Netley, and that portion of Hampshire which lies within the Aldershot Command—the practice of teaching quick disinfection spread, and the incidence of venereal disease fell very low, especially in 1919. In that area, however, were many highly infected troops—American, Colonial, and R.A.F., who did not belong to the British Army, and therefore were not instructed. Moreover, into the area came highly infected drafts from other areas, and whole units from overseas. Consequently, the local military authorities, proud of their results, compiled records which carefully distinguished disease acquired by the instructed troops from that acquired by the rest.

In 1919 the Ministry of Health appointed an Inter-departmental Committee ostensibly to inquire into the best methods of reducing the prevalence of disease. Carefully selected evidence from an army which had not used disinfectants as disinfectants was adduced to prove that disinfectants used as disinfectants were useless. The Committee was especially shocked to find that soldiers who had been taught to use disinfectants for early treatment had actually so used them.

The scandal of this committee led immediately to the foundation of the Society for the Prevention of Venereal Disease. The President of the latter, Lord Willoughby de Broke, raised a debate in the House of Lords (December 10th, 1919), and asked for information about the Portsmouth area. Lord Sandhurst, speaking for the Ministry of Health, replied that the incidence of disease in the area (not the town) had before 1919 been twice, and in 1919, two and a half times, as great as in the rest of the kingdom. I had local knowledge, and at once pointed out the error that Lord Sandhurst's figures were monstrously incorrect. Thereupon (February, 1920) the Ministry of Health issued a White Paper in which it was admitted that a great mistake had been made. It seems that Lord Sandhurst's ingenious statistician had taken all the

disease in the area—in the British army and out of it, imported and locally acquired—and attributed it all to the *small garrison of the town*. Thus had he reached the tremendous figure of 163 for the area. Actually in 1917 the figures for the town were 92 per 1,000 per annum, but in 1919 they had fallen to 54.4 for the town and 47.3 for the area. In 1917 the figures for the whole country were 38; in 1919 they had risen to 64 owing to disease imported from overseas. No attempt is made in the White Paper to explain the *fall* in the Portsmouth town and area; but it is explained that the rate did not rise in the area (as in the rest of the country) because the area had no port of entry for overseas troops, and so was spared imported diseases. Actually Southampton, the largest port of entry, is a mere *enclave* in the area, and normally part of it, but separated from it during the war for administrative purposes. Not a man left Southampton by land but passed into the area, and all men for whom accommodation could be found stayed in the area. Its barracks and camps were flooded with overseas troops, and its hospitals swamped with their diseases. By far the greater part of the figures 54.4 and 47.3 was due to imported disease.

Such is the use that the Ministry of Health made of statistics. It has been suggested that it was misinformed. But about what precisely was it misinformed? About the fact that soldiers were told to use disinfectants for early treatment? About the attribution of the disease of the whole area to the small garrison of the town? About the geographical situation of Southampton? About the fact that the hospitals of the area were swamped with imported disease? I am aware that I am making very serious charges. But the Ministry of Health has long been accused of misrepresentation; it has long had all the facts in its possession; if I am anywhere in error, it could long have demonstrated that error very easily; it has not made, and it will not make the attempt. Meanwhile will Dr. May inform us why he supposes that the soldiers in Germany are better instructed than those in the United Kingdom?

The following figures are not mine, but taken from official sources. Before the war 10 per cent. of the inhabitants of the great towns suffered from syphilis. Gonorrhoea is many times more common. Both have greatly increased since the war. Seventy-nine per cent. of the population is urban. On an average from 50 to 100 exposures of men to danger result in one infection. Ordinary women are, of course, less diseased than prostitutes; yet three out of four soldiers acquire their infections from the former. From all this some idea of the extent of immorality and disease in the country may be gathered. Venereal disease is immensely the largest source of waste among us—waste of life, health, happiness, and wealth. Why is immorality so prevalent? Because, notwithstanding all the declamation about morality, no real attempt has ever been made to teach it. If any reader of the BRITISH MEDICAL JOURNAL examines his past, he will find that he learned about sex from boys and that the opinions which he had acquired by the time he reached puberty are, for good or evil, very nearly those which he now holds. As the twig is bent, so the tree grows. Mere preaching to adults, which is all that is practised, is totally ineffective—as again the reader will find if he examines his own consciousness. It is this happy condition of affairs that Dr. May fears will be disturbed by the teaching of quick disinfection. Why is venereal disease increasingly prevalent? For two reasons: On the one hand, much easily preventable disease has been imported from abroad. On the other hand, a campaign of publicity, proclaiming the horrors of disease without any attempt at prevention, has diverted the attention of men, bound under the present system of teaching to be immoral in any case, from the prostitute to the amateur.—I am, etc.,

Southsea, Jan. 17th.

G. ARCHDALL REID.

SIR,—Dr. Otto May's letter appearing in your issue of January 8th, stating "that the broadcast issue of their (the Society for the Prevention of Venereal Disease) instructions implies a sanction to immorality on the part of the community" (his italics), and that "the balance of available evidence is against the efficacy of this form of prophylaxis," is difficult to reconcile with his opinion as

expressed in his introduction to his book *The Prevention of Venereal Diseases*, pages 12 and 13, which reads:

"Medical science can furnish means of aborting or preventing the development of disease in those who run the risk of infection, and in so doing medicine is fulfilling perhaps its greatest function, that of preventing rather than of attempting to cure disease. It is particularly *unfortunate* [my italics] that many people regard such methods of preventing venereal disease (artificial prophylaxis) as ethically wrong, maintaining that they condone or even encourage immorality."

Perhaps the readers of the BRITISH MEDICAL JOURNAL may consider Dr. May's gymnastics more difficult to reconcile with logical argument than my "heroics." That the Society for the Prevention of Venereal Disease are most anxious that their propaganda should not be taken as "implying a sanction to immorality," but only as a recognition of regrettable but indisputable fact, is shown by the following quotation from the leaflet issued under our authority by the Shipping Federation for the instruction of merchant seamen in immediate self-disinfection: "Distribution of these packets does not imply a sanction to misconduct."—I am, etc.,

London, W., Jan. 13th.

H. WANSEY BAYLY.

SIR,—I am grateful to Lord Willoughby de Broke for his unequivocal statement of the policy of the Society for the Prevention of Venereal Disease, that all boys and girls who have reached the age of puberty "should have access to the latest scientific knowledge of this subject" (venereal prophylaxis).

As a policy it has the merit of being comprehensive but its consideration opens up curious vistas of the future education of the young. I do not think I can be accused of parody in drawing the following domestic scene in household "having access to the latest scientific knowledge" as purveyed by the Society for the Prevention of Venereal Disease:

Mary (aged 14, going off for the day to a choir picnic): Good bye, mother.
Mother: Good-bye, dear. Have you got all you want? You haven't forgotten the permanganate, have you?
Mary: No, mother; it's in my bag all right.
Mother: And, don't forget, if anything *should* happen, mind you use it *at once*.
Mary: Never fear, mother; I've got the book of the words, and I don't intend being caught out.

A pleasing peep at the manners and customs of post-war England.—I am, etc.,

London, N.W., Jan. 18th.

OTTO MAY.

RISKS AFTER OPERATION ON TONSILS AND ADENOIDS IN OUTDOOR CLINICS.

SIR,—It will surely be impossible to countenance existing conditions in the face of the numerous letters from influential oto-laryngologists in charge of hospital clinics in Manchester, London, Bristol, Plymouth, York, Portsmouth, Maidstone, while to these I could add equally forcible opinions privately expressed by many colleagues in charge of clinics in many other centres all combine in supporting Mr. Eric Watson-Williams's contention that the risks of complications following these operations are greatly increased when children are sent back straight to their homes instead of being taken into hospital, and of which the figures he cites afford such convincing evidence.

What are the avoidable risks and complications cited by your correspondents? Sir William Milligan says:

"Deaths from the anaesthetic are still too frequent, while complications—for example, acute otitis media, acute mastoiditis, glandular infection, haemorrhage, etc.—are practically unknown if the child is kept in bed and properly nursed for two or three days."

Mr. Herbert Tilley, having experienced the occasional complications Mr. E. Watson-Williams outlined, has adopted the plan of handing printed directions to the parents. Such printed directions are similar to those for a long time used in other clinics and are to be commended; they have an excellent effect in reducing the number of avoidable complications. Better far, however, is the plan followed by the Portsmouth and Southern Counties Hospital, where a certain number of special beds were set apart for these cases in children.

Deaths, acute otitis media (a prolific cause of permanent deafness in after-life), bronchopneumonia, acute sepsis avoidable, and attributable to operating under condition.

which are preposterous! Are we to continue the infliction of such complications because there is a shortage of adequate accommodation in existing hospitals, and without any appeal to the community at large to alter the conditions? Thousands of beds could be made available to-day in different areas, in Poor Law hospitals, where clinics could be established in charge of specially trained and experienced surgeons. Parents very naturally resent the stigma attaching to Poor Law infirmaries, but, surely, the stigma is a figment wherever enlightened and broad-minded guardians have organized their infirmaries on worthy lines.

Moreover, there are comparatively few working men and women who would not rather have their small children operated on under safe conditions in a Poor Law infirmary if the only alternative was having them sent back to their crowded homes, with far greater risk of dangerous complications, if they only understood what those dangers were; and further, a large proportion of those parents of the hospital class would be willing and able to defray, more or less completely, the cost of operations under such conditions.

If a municipal fever hospital, rate-supported, is available for the ratepayer, why should not the same ratepayers find hospital accommodation for these little children in the hospitals under the charge of guardians? The guardians can charge the relatives of these children the cost of their maintenance and treatment, as far as they are in a position to meet those charges.

We have been waiting year after year for "something to turn up," while these children are needlessly subjected to very useful and very necessary operations under conditions which are neither useful nor necessary, if only we were not so hidebound by prejudice and ridiculously out of date tradition. And it is difficult to avoid the conclusion that the real and essential obstacle lies not in an impasse, but in the medical profession failing to make known far and wide the true facts and issues at stake.—I am, etc.,

P. WATSON-WILLIAMS, M.D. Lond.,

Lecturer on Otolaryngology and Laryngology, University of Bristol, and in Joint Charge of the Ear, Nose, and Throat Department, Bristol Royal Infirmary; President, Bath and Bristol Branch of the British Medical Association.

TUBERCULOUS MILK.

SIR,—It was gratifying to read in your issue of January 1st the resolution passed by the Welsh National Memorial Association. I did not think when opening this correspondence that it would produce such rapidly satisfactory results. In this respect a distinctly beneficial function of the BRITISH MEDICAL JOURNAL is demonstrated.

That there is considerable diversity of opinion on the question of the immunization value, if any, of tuberculous milk is evident. One objection, however, to discussing matters such as this in the JOURNAL is that views expressed by medical men, which have potential commercial possibilities, may be made use of by the trade journals concerned. The correspondence has shown that the publications of the dairy trade have made such use of matter from it supporting the present "laissez faire" policy of many dairy farmers, thus helping to defeat the object one had in view in opening this discussion. Fortunately there are many brilliant exceptions to the average dairyman, notably the members of the British Friesian Cattle Society; it is to be hoped that in time the exception will become the rule.

From the scientific point of view your leading article of December 11th, 1920, ably and clearly sums up the present position. It is shown that much patient research is yet required in both the veterinary and medical sides. Your conclusions are that bovine tuberculosis is a menace, and that children should be protected from it; with these the majority of medical men are agreed; that the views of the minority should get so much prominence is unfortunate but human. It is felt, however, that some official pronouncement in plain language, intelligible to medical practitioners and laymen alike, would strengthen the hands of medical officers of health and tuberculosis officers at the present moment.

There is a general impression amongst farmers that the Milk and Dairies (Consolidation) Bill has been, not postponed but scrapped. No doubt the strong opposing interests will see that it is finally disposed of unless those concerned show there is an unquestionably urgent need for

its provisions. In this month's *Public Health* a report of the Council of the Society of Medical Officers of Health states that the matter has been taken up. It is first being dealt with in detail by the Tuberculosis Group, whose considered findings will no doubt be fully endorsed by the society. It is to be hoped that this official statement will receive a wide publicity in the medical, dairy trade, and agricultural journals, and also in the daily press. To those of us who are in daily contact with the milk problem the task seems herculean; nevertheless, there is no valid reason why this country should not become free of tuberculosis in cattle as the island of Guernsey has. The Royal Veterinary College at Camden Town has just inaugurated a campaign with this end in view. Tuberculin for tests and all necessary advice will be given to owners of pedigree cattle.

Finally, Mr. Editor, I wish to thank you for allocating so much of your valuable space to the discussion on this important subject.—I am, etc.,

S. NICOL GALBRAITH,
Medical Officer of Health.

Mid Notts Health Area, Newark-on-Trent,
Jan. 12th.

THE BEGINNINGS OF LIFE.

SIR,—The letter of Surgeon Commander W. Bastian, R.N., inspires me, as a worker on the same subject, to express a word of admiration of the genius of his father, Dr. Charlton Bastian.

Men of genius in research everywhere in science, or in literature, are men of imagination who make brilliant hits, and equally glorious mistakes, so that even as regards the latter one might say, if the Creator did not make it so, well He might have made it so.

Charlton Bastian was such a genius and absolutely devoted to his work, witness how while still possessed of virile strength he entirely gave up an important consulting practice to rusticate himself and pursue that quest of the origin of life that his soul loved. I visited him in his rustic haunts, and was shown his work, and can testify that he knew the part played by light, although I do not think that the products obtained by him were living organisms. But what does this matter to the living thought beneath?—along some such paths life first appeared.

There is no real opposition between Dr. W. Bastian's suggestion and that contained in the leading article of December 25th, as to where life started.

The important point is that the first approach to life must have been self-supporting. There probably were, and may be now, very simple organisms devoid of chlorophyll, or any complicated colour scheme, which could capture sunshine, but such organisms are quite different from those fungi and bacteria which sunshine kills. These latter draw their nutriment from organic matter and cannot live in its absence. Chlorophyll and its compeers are colour screens to protect the delicate photosynthetic mechanism underlying them. They are not the active agents; they are the blinds behind which the active agents work. The serried row upon the seashore of green weeds first, then brown weeds, then red weeds, teaches us this important fact.

In the depths of the Lake of Geneva there is said to be a white or colourless alga. I want to obtain it and see if in dim light it would photosynthesize. Along with my colleagues at Port Erin I have already found that red seaweeds work fastest in dim light; the light of June and July is too great even for the green seaweeds. The same variation in intensity of light which calls forth the vernal outburst in the sea evokes it also upon the land. For many years it had puzzled me in the midst of winter, looking at the dry twigs on the branches, how a new spell of life came to them and the buds swelled out and the fresh green leaves came, just as we all hope to see them soon.

Last spring, in a morning walk over Hampstead Heath, it came to me. Every schoolboy who has ever peeled a wand knows there is a green layer under the outer bark of brown or grey or yellow. The botanist calls it "concealed chlorophyll"; but is it concealed? It delighted me to strip off this layer of outer bark and hold it up to the sunlight and see that the light was breaking through. The violet and blue rays which are inimical to living cells were shut off, but all the others came through. Long

before the buds come and the new green leaves appear photosynthetic processes are already at work under the bark. This I have proven in a score of different trees. What is it, however, that gives the signal to the snowdrop and squill under the brown earth that the god of day is shining a little more every day and that it is now time to awaken? I would I knew. It is no good to call it habit. It must be conditioned by some seasonal stimulus. Does some solar radiation other than visible penetrate beneath the soil and awake the bulbs to their vernal outburst?

The letter of my friend Dr. F. J. Allen also greatly interested me. We have independently been thinking and working upon very similar lines.—I am, etc.,

BENJAMIN MOORE.

Laboratory of Biochemistry, University of Oxford,
January 10th.

SIR,—Your leading article of Christmas week on the beginnings of life once again brings into prominence the question of abiogenesis. Despite its great interest, this question of the time, place, and *modus operandi* of the origin of living matter has hitherto been so deplorably shunned by scientific men—always, of course, with the signal exception of the great neurologist, Charlton Bastian—that it is gratifying to learn that a biochemist of such eminence as Professor Benjamin Moore is now engaged on research work in it. For some years I have been carrying out certain experiments in connexion with the absorbing questions as to how living matter first arose in the past (archebiosis), and as to whether it does or can evolve from non-living matter to-day (abiogenesis). It is difficult to agree with the contention in your last paragraph that the golden key to unlock the long-closed door between non-living and living matter is to be wrested from such relatively highly differentiated forms of life as the algae; moreover, the further inference in the same paragraph that bacteria can only exist on organic matter is surely incorrect. There are many kinds of bacteria capable of living on inorganic materials. I have kept such prototrophic micro-organisms for several months, and seen them flourish and multiply in water containing no other food supply than dissolved gases and inorganic salts.

The experiments alluded to above were conducted on the general lines indicated by Charlton Bastian, who, shortly before his death, was good enough to furnish me with certain suggestions relating to them. They differ, however, from those of Dr. Charlton Bastian in that inorganic solutions only were used. For sterilization of the hermetically-sealed tubes reliance was placed on the high temperature of steam under pressure in an autoclave, after which, at and for varying intervals of time, the sterilized contents were exposed to the energizing influence of heat, light, and electricity. It must be confessed that, up to the present, these experiments have yielded negative evidence of the development of living matter. The tubes when opened—even after the lapse of years—showed sterile contents, yet some twenty-four hours after opening, the inorganic medium was swarming with living organisms. There is, however, always the hope that success will attend future experiments when science has succeeded in bringing the microcosmos—as represented by the sealed tube with its miniature ocean of water and salts and its miniature atmosphere of gases—into better approximation to those conditions which existed in the macrocosmos as represented by the primate world when living matter first appeared on its stage.—I am, etc.,

C. MARSH BEADNELL,
Surgeon Captain R.N.

Royal Naval Hospital, Chatham,
Jan. 9th.

GLANDULAR FEVER.

SIR,—I read with much interest Dr. Tidy's letter on glandular fever (p. 100). There is no doubt that the disease is quite common and more attention should be paid to it. I described an epidemic occurring in my own practice in the BRITISH MEDICAL JOURNAL of January 24th, 1914. Since then I have had several outbreaks presenting the same features. The real interest of the disease lies in the nature of the infection. Surely this could be settled by the excision or puncture of one of the glands. It has been suggested that it is an attenuated bubonic plague, which does not seem very probable.—I am, etc.,

A. CAMPBELL STARK.

Wanstead Park, Jan. 16th.

TREATMENT OF THE PRE-OPERATIVE STAGE OF ENLARGED PROSTATE.

SIR,—The valuable remarks of the distinguished urologist on this subject in the JOURNAL of January 15th call for some criticism in a few directions. With your permission I shall take up three. First, it is quite apparent that operation is urged in all cases allowing of it; second, that the disease is progressive; and third, that a certain symptom—frequency of micturition—is pathological (necessarily so).

Taking the last first, in my experience there is scarcely a man or woman over 50 who does not urinate once or oftener at night. So common is it in the absence of gross lesion that I attribute it to waning tone in the sphincter vesicae.

Then as to the second and first points: prostatic hypertrophy is not usually a progressive disease after a certain stage is reached, despite the view to the contrary. I have patients under my care whom I first attended for this state twenty years ago, and they are not worse now than at the beginning or when I first saw them. Is every poor old fellow with enlarged prostate—a condition so common as almost to be thought natural, and there are no prostates quite normal after 55—to be urged to operation? Is there no better way for some?

In my opinion no man should have his prostate removed unless his symptoms are progressing, or are spoiling his health, or unless the salient state is obstruction. True, if he likes to be in fashion, and deems himself pretty sure of the company of some 94 or 95 who recover, let him take the small risk; but to be amongst the other party of five or six is a poor exchange for a malady which never may seriously trouble him.

Congestion and oedema of mucous membrane cause most immediate trouble. No one who has not conscientiously tried palliative treatment should disregard it. Many of my patients are using with the greatest benefit hot and cold douching combined with massage by a special instrument I got constructed. It consists of a large perforated bulb. It is as necessary to massage the prostate from apex back as it is from base forward. One pressure forces secretions out, the other aids the veins. With many more I use sounds and instillations. Amongst drugs, ergot, salix nigra and their class often do much good. To do these things gives some trouble, but scarcely more than a shave. "Adenomatous" prostate is, I fear, a misused term in many cases.

As to treatment, the chief point is to distinguish irritation from obstruction.—I am, etc.,

London, W., Jan. 16th.

JAMES MACMUNX.

X-RAY RADIATION IN CANCER.

SIR,—Mr. Sampson Handley, in his Association lecture on the lines of advance in the surgery of breast cancer, reported in the JOURNAL of January 8th, urges the use of x rays, perhaps before, and certainly after, operations for breast cancer. He indicates that their value depends on the doses in which they are given, and suggests that harm may be done both by under- and over-dosage—in the first case by stimulating the growth of cancer cells, and in the second by breaking down the patient's (or experimental animal's) resistance.

Since 1905 I have been asking a colleague who undertakes x-ray treatment what dosage he employs in these cases, and I find that not only cannot he himself tell me, but that x-ray specialists to whom he has repeatedly referred the question at various times have not apparently framed a scheme of treatment by accurately measured doses, and seem to work more or less by rule of thumb.

It would add to the confidence of those who advise x ray treatment if Mr. Handley would state in quantitative terms what he considers to be the optimum doses for the cases under discussion.—I am, etc.,

Colwyn Bay, Jan. 11th.

ROBERT E. LORD.

SIR,—Mr. Sampson Handley's lecture which you published in the JOURNAL for January 8th is of profound importance, not only from a surgical but also from the radiation point of view. It is the latter that especially interests me.

It is really refreshing to note the emphasis which a surgeon of Mr. Handley's pre-eminence in the special

department of surgery on which he is writing lays on radiation. This method of improving the chances of patients operated on for breast cancer is not nearly so commonly carried out as it ought to be. Its neglect is, of course, due to the surgeon's lack of recommending it in connexion with his surgical procedure.

I have carefully observed for many years the results of surgery in breast cancer without radiation, and with ante- or post-radiation, or both. There is no doubt in my mind that both ante- and post-radiation are very desirable, and enormously improve the patient's chance of increased length of life. I think that x-ray radiation is generally the most applicable. This must be done through aluminium filters, and ought to be applied in "massed" doses.

Mr. Handley says that "the practice of giving large doses of x rays prior to operation is probably a sound one, though its value is not easily susceptible of proof." This is true. Might I suggest that the action is of several kinds? The cancer cells in the lymphatics are probably "fixed" by the radiation; some of the isolated cells in these regions are sterilized; and at the same time an immunizing agent is produced in the tissues which lessens the power of small colonies of cells to further proliferate. The latter is probably a form of ionization produced in the tissues by the action of the x-ray radiation.—I am, etc.,

London, W., Jan. 17th.

JAMES METCALFE.

THE TEACHING OF ANATOMY AND PHYSIOLOGY.

SIR,—The criticisms of Professor Berry, in his paper on the teaching and study of human anatomy in your issue of January 15th, call attention once more to the defects in an important part of the medical curriculum. There is room for improvement in the correlation of the different branches of medical science throughout the curriculum, but at no time, in my opinion, is this more patent than in the early years.

Anatomy and physiology are too often taught as subjects unassociated with the later clinical work; this detachment is further emphasized by the medical school and hospital being separate buildings, often at a considerable distance from one another; and by what is of more significance to the student, the all-important intervening event of an examination. The successful candidate breathes a sigh of relief, as much as to say at last he is coming to the real part of his education. This appearance of an abrupt cleavage in a student's career is obviously wrong. There is another ill effect, too, I think, in this disjointed method of teaching, and that is (especially as regards anatomy) it becomes largely a matter of stuffing the memory at a stage in a student's life when every effort should be made to educate observation, reasoning, and breadth of view. And, as Professor Berry points out, the memory is crammed with much that is of little practical use subsequently, and, as he might have added, the knowledge so acquired is in many respects fallacious, for it gives rise to an impression of inflexibility and rigidity of tissues (inseparable from the method of preservation of the bodies) and inferentially of their functions, which is quite at variance with what is afterwards found to be the case when dealing with living material.

Sir Berkeley Moynihan, a few years ago, presented medicine with one of the really great gifts of modern times—namely, the conception of the pathology of the living. The extension of this idea to teaching throughout the medical curriculum goes to the very heart of the matter; and so far as anatomy and physiology are concerned the obvious remedy is to set students to hospital work at the time they now begin anatomy and physiology, so that these subjects might be taught concurrently with clinical work. I doubt whether teachers of the present generation would be capable of giving quite the right kind of instruction, except perhaps by team work. But in the future, and little by little, knowledge would develop on the lines on which the preceding generation had been taught; teachers would then be able to expound the principles of anatomy and physiology in their clinical bearing in a way that is at present scarcely possible.

This principle of overlapping and correlating could be very well extended to all other aspects of medical education, and if it should be argued that the available time would forbid, I think there are some subjects included in the present curriculum which might very well be curtailed or deleted as special subjects—to mention two,

materia medica and therapeutics; all that it is necessary to know of these could be satisfactorily incorporated with physiology and bacteriology—to the benefit, I venture to think, and undoubtedly to the unspeakable delight of the student with his over-taxed memory.

Another way of utilizing time more profitably would be to dispense with all systematic lectures; these have a soporific rather than a stimulating effect on most students, and the knowledge which it is intended to convey in this manner could be more usefully and interestingly imparted either at clinical lectures or at the bedside.—I am, etc.,

E. R. FLINT,

Leeds, Jan. 16th. Surgical Tutor, General Infirmary, Leeds.

FATAL POISONING FROM INHALATION OF ACID FUMES.

SIR,—The cause of the fatal poisoning by acid fumes, which Dr. T. G. Moorhead reports in the *BRITISH MEDICAL JOURNAL* of January 15th, is somewhat obscure, and as he no doubt wishes to invite some observation which may tend to clear up the unexpected fatality, I venture to offer the following remarks:

Among the exercises that Dr. Moorhead mentions was the identification of Sb_2S_3 (stibnite). Under ordinary circumstances the action of pure H_2SO_4 on stibnite would not produce a poisonous gaseous product, but if a metal happened to be present nascent hydrogen would be developed, which would act upon the Sb of the stibnite, producing stibine (SbH_3), a gaseous and highly poisonous product. I hope this may lead to an elucidation of this fatality.

Another explanation may be afforded by the quality of the H_2SO_4 used; if it contained As_2O_3 as one impurity, an analogous reaction would take place in the presence of a metal, in this case arsine (AsH_3) being formed.—I am, etc.,

NINIAN M. FALKNER, M.D.,

Vice-President, Royal College of Physicians of Ireland.

Dublin, Jan. 17th.

THE STUDY OF HEART DISEASE.

SIR,—Last November, at a meeting of the Medical Society of London, it was agreed that heart disease is more prevalent among the children of the poor than among those of the well-to-do, but no answer was forthcoming to the question why?

The admission implies that a difference of conditions is responsible for this greater incidence, and if we could but settle the point wherein that difference lies we would achieve something of very great national importance.

We have to admit that Jewish children living in the slums have as good a health rate as that of wealthier children, from which we must infer that poverty, as such, is not a cause, for the houses in which the former live are not good, their clothes are secondhand, and dirt abounds, but their Kosher food is first-class. Can we establish the fact that in the poorness of the food lies the cause of the greater tendency to rheumatic fever and chorea amongst the Christian poor?

The question on which I lay great stress is whether children get sufficient lime-bearing foods, such as milk, eggs, or cheese, in the ash of which calcium forms a high percentage. Some children cannot get them, others cannot take them, preferring salty and acid foods, and I cannot but think that until they all can and do take them so long will this great tendency to rheumatic fever and chorea exist.

Our milk supply requires overhauling, and we need to encourage fowl-rearing if progress is to be reported, but increased production of all sorts is the secret of national success.—I am, etc.,

Swansea, Jan. 16th.

G. ARDOUR STEPHENS.

THE NAVAL MEDICAL SERVICE.

SIR,—The letter by "Action" on this subject in your issue of January 8th is very much to the point. Letters lead nowhere unless followed by action. I fear, therefore, unless the Naval Medical Service can elicit sympathy and help from outside it is up against a blank wall. To my mind there are two fundamental reforms essential before any real improvement is possible. The first is that the Medical Department of the Admiralty must have entire charge of its own affairs; for instance, until medical promotions and appointments are entirely in the hands of

medical men, progress is extremely difficult for obvious reasons which I will not press. Secondly, medicine must be represented on the Board of Admiralty. Surely, after the experience of the past few years, all combatant officers realize what an enormous factor in winning a war efficient medical and sanitary organization has become and how the importance of this factor will tend to increase as medical science advances. This being so, how can any board consider itself fully competent to control a fighting service without medical representation?

Should the above reforms ever materialize, it follows that other grievances, professional and financial, will become much easier to rectify. Discontent is a drag on the efficiency of any body of men, and everything in reason should be done to remove it. It is no exaggeration to say that the Royal Naval Medical Service is at the present time seething with discontent: a fact which saddens anyone who has the welfare of the Senior Service at heart. —I am, etc.,

January 9th. *

"ANXIOUS."

The Services.

THE ARMY OF THE BLACK SEA.

IN the dispatch, just published in the *London Gazette*, from General Sir G. F. Milne, Commander-in-Chief of the Army of the Black Sea, it is stated that the health of the troops has been good, the greatest zeal, foresight, and skill having been displayed by the R.A.M.C., under the Director of Medical Services, Major-General Sir M. P. O. Holt, K.C.B., K.C.M.G. By July, 1919, most of the men suffering from malarial relapses had been sent home, and there had been practically no primary malaria since the army left Macedonia. Besides purely military duties, it had been necessary for the medical services to undertake, in conjunction with our allies, the sanitary supervision of the port and town of Constantinople—a task of peculiar difficulty owing to the constant transit of refugees and the many epidemics prevalent in that part of the world. The Inter-Allied Sanitary Commission, which supervised this work, was presided over first by Colonel W. H. Nickerson, V.C., C.B., C.M.G., and later by Major-General Holt, D.M.S. The health of the population and the absence of epidemic disease were the best testimony to the work of this Commission. They gave devoted services also to the sick refugees and wounded from South Russia, numbering some 10,000. General Milne records, likewise, his appreciation of the excellent work performed by Queen Alexandra's Imperial Nursing Service, and by the ladies of the Voluntary Aid Detachments.

The names of the following additional medical officers are mentioned for distinguished and gallant services:

Captain and Brevet Major (acting Lieut.-Colonel) R. E. Bernsley, M.C., and Captain W. Bird, of the 84th Field Ambulance, R.A.M.C.; and temporary Captain H. C. Mitter, 84th Field Ambulance, I.M.S.

MINISTRY OF PENSIONS: THE "OFFICERS' FRIEND."

WE are asked to announce that disabled officers and nurses who served during the great war, and widows and dependants of officers deceased can obtain helpful advice and information regarding their rights under the regulations of the Ministry of Pensions, by applying to the "Officers' Friend," Ministry of Pensions, Cromwell House, London, S.W.1, or the "Officers' Friend," at any of the Regional Offices of the Ministry, Burton Court, Chelsea, S.W.1; Newcastle-on-Tyne; Manchester; Bristol; Leeds; Nottingham; Birmingham; Edinburgh; Dublin; Belfast; or Cardiff.

HONOURS.

ORDER OF THE BRITISH EMPIRE.

THE following appointments to the Order of the British Empire are announced for services in connexion with the war:

O.B.E. (Civil Division).—Dr. M. A. Johnston de Lavis Trafford, senior medical officer, Red Cross Hospital, Turin.
M.B.E. (Civil Division).—Dr. W. L. Chubb, medical officer, Minley and Farnborough Court Auxiliary Hospitals, Farnborough; Dr. Edmund Lloyd, a Church Missionary Society doctor in charge of relief and hospital work at Gaza.

DEATHS IN THE SERVICES.

LIEUT.-COL. STANDISH DE COURCY O'GRADY, C.M.G., D.S.O., R.A.M.C., died at the Military Hospital, Malta, on December 23rd, aged 47. He was born at Dresden on July 27th, 1872, and educated at Trinity College, Dublin, where he graduated M.B., B.Ch., and B.A.O. in 1896. Entering the army as surgeon lieutenant on July 27th, 1898, he became captain in 1901 and lieutenant-colonel on March 1st, 1915, and was appointed temporary colonel on October 30th, 1916. He had also qualified as a specialist in State medicine at the R.A.M.C. College. He was served in East Africa in the Somaliland campaign of 1904, mentioned in dispatches in the *London Gazette* of September 2nd, 1904, and received the medal with a clasp. In the recent

war he was thrice mentioned in dispatches: in the *Gazette* of February 17th, 1915, May 29th, 1917, and December 30th, 1918; received the 1914 star, with the war medal and the Victory medal, the D.S.O. on June 3rd, 1917, and the C.M.G. on January 1st, 1919.

Obituary.

JOHN WILLIAM SIMPSON, M.D., F.R.C.P. EDIN.,
Physician, Royal Edinburgh Hospital for Sick Children.

ON January 11th the news of the death of Dr. J. W. Simpson came as a sudden shock to medical circles in Edinburgh. Dr. Simpson, it was known amongst his friends, had undergone a serious operation some months ago, but he had made a good recovery, and hardly any one knew that he had been attacked with pneumonia until that disease proved fatal in some four days. His death falls heavily upon the Royal Edinburgh Hospital for Sick Children, of which he was one of the physicians; for within a very few years this institution has lost by retirement, by death, and by removal from Edinburgh no fewer than five of its senior medical and surgical staff.

Dr. Simpson was educated at Dollar and later at the Edinburgh Royal High School. He then passed to the University of Edinburgh, where he graduated as M.B. and C.M. in 1896, and as M.D. in 1906. He became a Member of the Royal College of Physicians of Edinburgh in 1899 and was elected a Fellow in 1903. He held several medical posts in Edinburgh in the years following upon his graduation, such as house-surgeon, house-physician, and house-surgeon to the eye wards in the Royal Infirmary, and physician to the Cowgate Dispensary. Then he was appointed registrar and resident medical officer to the Hospital for Sick Children, and finally became one of the physicians to that institution. During the years in which Dr. Simpson was holding these appointments he was also building up an excellent consulting practice in the diseases of children, and was making several additions of value to the literature of that subject, of which the most outstanding was his *Guide to the Feeding of the Infant during the First Year*. He also contributed articles on infantile maladies to the *Edinburgh Medical Journal*, to the *Scottish Medical and Surgical Journal*, and to the *BRITISH MEDICAL JOURNAL*, and in every case his contribution contained facts worthy of record.

To many in a wider circle Dr. Simpson was known and admired as a Rugby football player of the first rank; he shone in the nineties of the last century in many a stubborn contest, both for his old school (the Royal High School) and for his country in international games, in thirteen of which he played against England, Ireland, and Wales. He continued in touch with the game after ceasing to play by acting first as a member and later as the president of the Scottish Rugby Union Committee. He added fishing and golf to the outdoor sports of which he was fond; and in his passing to and fro in the streets of Edinburgh one could not fail to note the swing and the lithe strength of the athlete. To many patients and to a large circle of friends Dr. Simpson's death will be a real bereavement. The funeral, at the Dean Cemetery, took place on January 14th.

Universities and Colleges.

UNIVERSITY OF OXFORD.

Radcliffe Travelling Fellowship, 1921.

AN examination for a Fellowship of the annual value of £200, and tenable for three years, will be held during the present term, commencing on Tuesday, February 22nd, at 10 a.m. Candidates must not have exceeded four years from the time of passing the Final B.M. examination. The successful candidate must before election declare that he intends to devote himself during the period of his tenure of the Fellowship to the study of medical science, and to travel abroad with a view to that study. The examination will occupy four days. Papers will be set in physiology, pathology, and preventive medicine, and a subject will be proposed for an essay; there will also be a practical examination in pathology. Any candidate desiring to offer in addition a special branch of either medicine or surgery must send notice of this to the Regius Professor of Medicine on or before February 2nd. All intending candidates should send their names, addresses, qualifications, etc., to the Regius Professor of Medicine, University Museum, on or before Wednesday, February 2nd.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

A QUARTERLY COUNCIL was held on January 13th, when Sir Anthony Bowly, President, was in the chair.

The President reported that the Prince of Wales would honour the College with his presence at the Hunterian Festival Dinner on February 14th, and receive the diploma of Honorary Fellowship, to which His Royal Highness was elected on July 24th, 1919.

The Diploma in Public Health was issued to thirty candidates found qualified by the Conjoint Colleges. In Tropical Medicine and Hygiene diplomas were granted to twenty-five candidates. In Psychological Medicine diplomas were issued to four candidates.

An alteration in the fees for the several examinations for the Licence in Dental Surgery was necessitated by changes in the regulations which have now come into force. Under these the examinations in general and dental anatomy and physiology are separated from the examinations in general dental surgery and pathology and form part of the first professional examination, and candidates who have passed the Preliminary Science Examination can present themselves for examination in general and dental anatomy and physiology after completing six months' study during the ordinary sessions at a recognized medical and dental school.

The Onodi Collection—The Council accepted this collection (of nasal anatomy) as a gift from the Onodi Committee, and undertook the preparing and mounting of the specimens for display. The thanks of the Council for the donation was accorded to the donors.

The French Academy of Medicine—A letter was read from Sir D'Arcy Power reporting the attendance of the College delegates at the centenary celebrations of the French Academy of Medicine in Paris on December 20th-23rd, and a letter from the secretary of the French Academy acknowledging the receipt of the address of congratulation presented by the delegates on behalf of the College.

Medical News.

A DINNER to Major General Sir Robert Jones, K.B.E., C.B., will be held on January 31st, at 7 p.m., at the Midland Adelphi Hotel, Liverpool, on the occasion of the presentation of his portrait by his old colleagues and friends at the Royal Southern Hospital, Liverpool. The Earl of Derby will preside. Tickets, £1 1s each, can be obtained from Mr. T. R. W. Armour, 42, Rodney Street, Liverpool.

THE Liverpool and District Overseas Medical Officers will hold their third annual dinner at the Midland Adelphi Hotel, Liverpool, on Friday, February 11th, 1921, when the Director General, Army Medical Service, Lieut. General Sir John Goodwin, K.C.B., C.M.G., D.S.O., hopes to be present. Tickets may be obtained from the honorary secretary, Captain G. F. R. Smith, 19, Queen's Drive, Mossley Hill, Liverpool.

THE annual dinner of the Hunterian Society will be held on Wednesday, February 2nd, at the Procadero Restaurant, at 7 p.m. for 7.30, with Dr. A. C. Jordan, President, in the chair. Ladies will be invited. The price of the dinner is 16s 6d, exclusive of wine.

WE are asked to state that the Council of the National Medical Union has made a protest against the regulations with regard to the new insurance record cards, which they consider involve a breach of confidence between the patient and medical adviser.

A PAPER on "Medicine in India" will be read by Dr. Cecil Webb Johnson before the Last India Association on Monday, January 24th, at 3.30 p.m., at 3, Victoria Street, Westminster, S.W. Sir Ronald Ross will preside.

FOUR lectures on communicable diseases will be delivered by Sir Robert Armstrong Jones at Graham College, Linsinghall Street, E.C.4, on January 25th, 26th, 27th, and 28th, at 6 p.m. Admission is free.

THE following course of Emeritus Lectures and Addresses has been arranged for the ensuing session at the Middlesex Hospital Medical School. Surgeon Rear Admiral Brassey Smith will lecture on February 1st, 3rd, and 8th on Mediterranean fever, malaria, and trypanosomiasis respectively. Sir Alfred Pearce Gould will lecture on February 22nd on "Surgery—a progressive science, the latest word is not the last word." Sir R. Douglas Powell will lecture on February 25th and March 14th on "The etiology of phthisis." On March 1st, 3rd, and 8th Dr. W. McCrankin will lecture on "The future of the medical profession." On March 11th and 18th Sir James Kingdon Fowler will lecture on "The treatment of tuberculosis," and on June 3rd Dr. C. Hubert Bond will lecture on psychiatry. Visitors are cordially invited to the lectures, which will be held in every case at 3 p.m.

A SESSIONAL meeting of the Royal Sanitary Institute will be held, jointly with the West of England Branch of the Society of Medical Officers of Health, on Friday, January 28th, in the Guildhall, Exeter, at 4.30 p.m., when a discussion on "The Sanatorium Question" will be opened by Dr. E. Ward, Tuberculosis Officer, Devon County Council.

THE annual general meeting and conversazione of the Harveian Society of London was held on January 13th. Dr. Turtle was elected president for the ensuing year. The retiring president (Dr. Hill) delivered an address on the great advances in the methods of treatment of disease of the oesophagus during the present century. The adjourned debate on the future of the Poor Law infirmary will be held at the Paddington Town Hall on Thursday, January 27th, at 8.30 p.m., when Dr. Stewart of the Paddington Infirmary and Dr. Dudfield, M.O.H. Paddington, will speak.

A SERIES of post graduate courses is being arranged at the Manchester Royal Eye Hospital to commence early in February. There will be three courses, each consisting of twelve demonstrations, they will deal with (1) external diseases of the eye, (2) diseases of the fundus oculi, and (3) refraction. The fees are £3 3s. for each course, and those proposing to join should communicate with the honorary secretary, 28, St. John Street, Manchester.

CLINICAL instruction in the treatment of venereal diseases will be given to general practitioners by Colonel L. W. Harrison in the Male Department (Hut E) of St. Thomas's Hospital, each Friday at 5.30 p.m. Admission on presentation of card.

Letters, Notes, and Answers.

As, owing to printing difficulties, the JOURNAL must be sent to press earlier than hitherto, it is essential that communications intended for the current issue should be received by the post on Tuesday, and lengthy documents on Monday.

ORIGINAL ARTICLES and LETTERS for consideration for publication are understood to be offered to the BRITISH MEDICAL JOURNAL alone unless the contrary be stated.

CORRESPONDENTS who wish notice to be taken of their communications should authenticate them with their names—of course not necessarily for publication.

AUTHORS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate with the Office, 423, Strand, W.C.2, on receipt of proof.

In order to avoid delay it is particularly requested that ALL letters on the editorial business of the JOURNAL be addressed to the Editor at the Office of the JOURNAL.

THE postal address of the BRITISH MEDICAL ASSOCIATION and BRITISH MEDICAL JOURNAL is 423, Strand, London W.C.2. The telegraphic addresses are:

1. EDITOR of the BRITISH MEDICAL JOURNAL, 4, Leicester, Strand, London, telephone 2630 Gerrard.

2. FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), Articulate, Westrand, London, telephone, 2630 Gerrard.

3. MEDICAL SECRETARY, Mediserv, Westrand, London, telephone 2630 Gerrard. The address of the Irish Office of the British Medical Association is 16 South Frederick Street, Dublin (telegrams: *Bacillus Dubin*, telephone 4737, Dublin) and of the Scottish Office 6 Putland Square, Edinburgh (telegrams: *Associate, Edinburgh*), telephone, 4361, Central.

QUERIES AND ANSWERS.

INCOME TAX.

"R.M." has received some inquiries from the local inspectors of taxes which are open to the construction that they are intended to elicit information as to the liability of the practitioner for whom our correspondent was acting during the war.

"We suggest that 'R.M.' might inform the inspector that as the information could doubtless be supplied with equal facility by the other practitioner he feels he must demur to giving the information unless the income tax authorities require him to do so, in which case the inspector can perhaps apply a reference to the statutory authorities. We have not previously had our attention called to an official request for particulars of payments made by one practitioner to another and very much doubt if the request has been justified.

"J.H.T." originally possessed a motor car for his practice; one was sold for £300 during his service in France and has not been replaced by a car of another make costing £1100.

"Our correspondent can treat as a professional expense that portion of the £1100 which represents the replacement of a car apart from any improvement in the old car. For instance, assuming that that car originally cost £450 and is the

date the new car was purchased for £1,100 would have cost £950, then of the £1,100 - £400 = £700, the net cost of the exchange of cars, £150 represents improvement and £450 replacement; this £450 is, of course, £950 (the supposed cost of the exact replacement) less the £400 received for the old car.

"M.D. CANTAB." has received the application for income tax and inquires why his earned income should be charged at 6s. in the £.

* * The rates of tax for earned and unearned income are now identical, the only difference in their assessment being the deduction of 10 per cent. (maximum deduction £200) in assessing the earned income. We therefore cannot say whether the 6s. charge is correct without further particulars of the assessment. These should have been shown on the earlier and more detailed "notice of assessment."

"ALPHA" asks for rather more information than can be adequately conveyed in a short note. The following, however, may assist him:

* * Tax is payable under Schedule A on the rental value of the house, and at the 6s. rate so far as that represents income passed on to the mortgagee, etc., under deduction of tax. One-half the rent and rates is presumably reasonable, but if only one maid is kept probably one-third of her wages and board would be enough. The child cannot be claimed for this year. The purchase of books, periodicals, etc., is allowable so far as incurred to maintain—not to create or improve—the practitioner's library.

"F. J." asks what allowances are due for supertax.

* * None; the "income tax" allowances do not apply to supertax, which is chargeable on the excess of the total income over £2,000.

"MEDICUS."—The calculation appears to be correct, except that as regards income from investments there is no allowance due for earned income. Consequently the amount repayable would be less than that suggested by £90 @ 6s. = £27.

LETTERS, NOTES, ETC.

THE HALF-YEARLY INDEXES.

THE usual half-yearly indexes to the JOURNAL, SUPPLEMENT, and EPITOME have been prepared and will be published shortly; they will, however, not be issued with all copies of the JOURNAL. Any member or subscriber wishing to have any or all of the indexes should communicate with the Financial Secretary and Business Manager, 429, Strand, W.C.2. Those wishing to receive the indexes regularly as published should also intimate their desire.

APPENDIX COMMUNICATING WITH COLON.

DR. CHARLES E. ETHERIDGE (Whitstable), in sending the following note, states that he can find no record of a similar condition. When making a post-mortem examination on an old woman of 65, who was found dead kneeling before her copper fire, the following condition of the appendix was found: The proximal end originated in the usual position on the caecum, but there was no free end, as the appendix curved upwards and joined the ascending colon on its inner side about an inch above the caecum. There was no thickening and no evidence whatever of any old inflammation, ulceration, or adhesions. The total length of the appendix was about 5½ in., and I was easily able to pass a pair of dressing forceps right through from caecum to colon, and from examination of the contents of the appendix there was evidently a free passage of liquid intestinal matter through this by-way.

"ONE WAY OF SELECTING A HEALTH RESORT."

DR. ANDREW ROSE (Bath) writes: With reference to the note under this heading in your issue of January 8th, I do not think Dr. Johnson Smyth's patient could have visited any of the graveyards in Bath before deciding permanently to reside in Bournemouth. He would, I venture to predict, find the tombstones to record an even higher percentage of persons dying at 81 and over than even in salubrious Bournemouth. Here it is not a very uncommon occurrence to find people living to well over the century. Indeed, only the other day a lady of 101 sent an autograph letter of birthday greetings to another Bath resident of 102. And even if Dr. Smyth's patient had taken a stroll through the city he would be surprised at the alertness and vivacity displayed by the ladies and gentlemen of from 70 to 80 and over, whom he would constantly come across, and who each day seem to get younger instead of older. Truly, Bath has a charm for old age.

TINNITUS AURIUM.

"J. J. A. N." (Natal) writes in reply to a request by "W. A. B." for information regarding tinnitus aurium in the JOURNAL of November 6th, 1920: I have found thyroid extract in gr. 23

doses night and morning to give the most satisfactory results in old patients. If and when improvement takes place, the dose should be lessened to one tablet at night, and the dose still further lessened as indicated by the progress of the case. Examination of the fundus should give some suggestions in "W. A. B.'s" case; this occurs to me because he mentions that the tinnitus is aggravated by lying down. Evidently there is a disturbance in pressure balance, vascular alone perhaps. I presume that the teeth are in order, and that the question of tobacco has been looked into. I might add that one is always glad to learn the results of carrying out suggestions.

TENNIS ELBOW.

IN the short correspondence in this column last year on the subject of tennis elbow reference was made to an article by Dr. Wm. Pearce Coues, but the writer of the note was unable to give the reference. We now have to acknowledge the receipt from Dr. Coues of a reprint of his article, which appeared in the *Boston Medical and Surgical Journal*, vol. clxx No. 13, pp. 461-465, March 26th, 1914. Dr. Coues admits that while the treatment of this condition is most unsatisfactory most authors agree that heat and fixation seem to be the best methods, with massage as a supplementary measure; six months of disability or, at least, of foregoing the chosen exercise must be looked for. He suggests that there might be two lesions causing the symptom-complex known as tennis elbow: first, a partial tearing of some of the muscular attachments from the extensor; second, the separation of bony spicules, the latter arising from such tearing; second, the joint capsule from antagonistic muscles, the supinator brevis and supinator longus. Lastly, Dr. Coues does not think that the theory of predisposition to arthritis deformans of the radial head can be accepted in all cases.

GRADUATED BOTTLES.

"SENEX" writes: It has often occurred to me that if panel chemists, either voluntarily or compulsorily, were to dispense all medicines for internal use in graduated bottles much trouble would be avoided. In common, I believe, with many of my confrères whose lines are cast in industrial areas, a large number of my panel patients swallow their medicine without regard to the dosage ordered. It is common knowledge that the working man's tablespoon holds much more than half an ounce (often double that quantity), and so he returns, Oliver-like, asking for more long before he is entitled to it. I am convinced that the charge of prescribing with undue frequency, resulting in a surcharge for "over-prescribing," would be made in fewer cases if graduated bottles were used.

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 33, 35, 36, 37, 38, and 39 of our advertisement columns, and advertisements as to partnerships, assistantships, and locum tenencies at pages 34 and 35.

THE following appointments of certifying factory surgeons are vacant: Chipping Campden (Gloucester), Kilbride (Bute), (Gloucester), Wansford (Huntingdon (Wilts)).

THE post of medical referee under the Workmen's Compensation Act, 1905, for the Sheriffdom of Stirling, Dumbarton and Clackmannan, is vacant. Applications to the Private Secretary, Scottish Office, by February 5th.

THE Record of the Save the Children Fund is published twice monthly, at a price of threepence, and contains an account of its activities for the relief of child distress and for assisting child-welfare efforts in nearly a score of different countries, from Britain and France to Hungary and China.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Six lines and under	0 9 0
Each additional line...	0 1 6
Whole single column (three columns to page)	7 10 0
Half single column	3 15 0
Half page	10 0 0
Whole page	20 0 0

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Tuesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive post-restante letters addressed either in initials or numbers.

EPITOME OF CURRENT MEDICAL LITERATURE.

MEDICINE.

104 Lumbar Puncture and Meningitis.

REGINALD WEBSTER (*Med. Journ. of Australia*, November 27th, 1920) records a series of experimental investigations into the part played by lumbar puncture in precipitating meningitis in animals rendered artificially septicaemic, and makes a plea for the conservative use of diagnostic lumbar puncture. As a result of his researches, he feels warranted in urging that the lumbar puncture needle should not be employed, except in the presence of definite clinical signs of meningitis, and in deprecating its use as a possible royal road to the diagnosis of an obscure condition. Lumbar puncture in the presence of a septicaemia may operate in two ways to promote infection of the meninges. (1) by impairing the integrity of the choroid plexus and meningeal lymphatics; (2) by extravasation of blood, which itself may be infective, within the cerebro spinal space. Haemorrhage within the dura mater, apart from infectivity, aggravates the effect of withdrawal of cerebro spinal fluid, for it is the equivalent of the "bland irritant" introduced into the spinal canal in the work of the different experimenters quoted. It is not suggested that spinal puncture, in the presence of a septicaemia, invariably leads to meningitis; but evidence is adduced to show that when conditions as regards severity of the septicaemia and pathogenicity of the causal organism for the meninges are favourable, there is a definite risk attached to the operation of lumbar puncture. As regards pneumonia in children, the fact that the clinician maintains a constant look-out for complications such as meningitis and arthritis, is a tacit recognition of the haemic nature of the pneumococcus infection, unless the bacteriological condition of the blood has been carefully investigated, a measure possible as a routine only in hospital practice, lumbar puncture should not be lightly undertaken. As long as the results of pneumococcal meningitis remain as disappointing as they are at present, the withdrawal of a cloudy fluid does nothing more than establish the diagnosis, there would be no objection whatever to the puncture if a purulent fluid could always be foretold, but how rarely does it materialize even when confidently anticipated? Once the decision to perform lumbar puncture has been reached, it would seem wise, unless the fluid is definitely turbid, to take off just sufficient for laboratory examination.

105 Pathogeny and Treatment of Diabetes Insipidus

NASSO (*La Pediatria*, September 1st, 1920) records the case of a girl of 8 years who developed, at 4 years, symptoms of diabetes insipidus, the average amount of water swallowed being from 11 to 14 litres and the average amount of urine passed from 12 to 15 litres in the twenty-four hours. Intramuscular injection of pituitary extract was followed by rapid improvement, the amount of urine falling to 4 to 5 litres a day and the amount of water taken to 3 to 4 litres. Nasso concludes that the pathogenesis of diabetes insipidus is connected with pituitary insufficiency, and that the treatment should be based on a proper use of pituitary extract.

106 Purpura in Cerebro-spinal Meningitis

ACCORDING to BONNAMOUR (*Lyon Med.*, December 13th, 1920), who records an illustrative case, contrary to what occurred in the United States during the epidemics of 1805-1811, in Ireland in 1866-67, and in Germany from 1886-87, purpura until recently has been very rarely observed in cerebro spinal meningitis in France, where it was noticed for the first time by Rist and Paus in 1902. Since then, and particularly since 1909, its frequency has decidedly increased, so that Netter found it in 13 per cent of the cases of cerebro spinal meningitis in 1913 and in 20 per cent in 1917. It was first observed at Lyons during the war, especially among the soldiers, while it remained rare among the civilian population. Purpura may appear at any stage of cerebro spinal meningitis. It most frequently appears between the second and fifth day of the disease, but it may precede the meningitis, or, as in Bonnamour's cases, be almost the only symptom of cerebro spinal meningitis which was not discovered till the autopsy. Lastly, though more rarely, purpura may occur by itself without any meningeal localization in association with septicaemic phenomena such as arthritis, fever, and

general disturbances. Lumbar puncture in such cases always shows a clear, sterile fluid, whereas blood cultures and examination of the petechiae yield meningococci. In a case of severe purpura lumbar puncture should always be performed and a culture made from the serum of the skin lesions, so that, if necessary, intrathecal combined with intravenous or intramuscular sero-therapy may be employed.

107. The Diphtheritic Heart and its Treatment.

AASLØ (*Lidskrift for Den Norske Lægeforening*, September 15th and October 1st, 1920) has studied the cardiac complications of diphtheria, and compared the mortality of this disease as treated at Ullevål Hospital, at different periods. He classifies his material in four groups, according to the extent and severity of the disease, and he finds that in the pre serum days—that is, between 1893 and 1894—the mortality was as high in the second group of cases as it was in the fourth group—that is, the most serious cases—treated with serum in the period 1915-1918. But though the increasing dosage of serum undoubtedly reduced the mortality, it did not banish the cardiac complications of diphtheria. Indeed, these would appear to be more frequent, and the author suggests that this fact may be correlated with the presence of 0.5 per cent. of carbolic acid in the serum used in Norway. Though some of it may be deposited as "carbolic acid albumin" and is filtered off, enough may be left to cause serious injury. In addition to prophylactic measures, such as absolute rest, morphine is an invaluable remedy for children as well as adults, reducing as it does restlessness and insomnia. Adrenalin given subcutaneously is remarkably effective in some cases, but useless in others. An ice bag placed over the heart sometimes has a definitely stimulating effect on the heart and also exerts a restful influence, particularly in children. It is also necessary to keep the organism adequately flushed with fluids.

108. Familial Spastic Paraplegia.

DE STEFANO (*La Pediatria*, October 1st, 1920) gives an account of two families in one of which four members and in the other two were affected by spastic paraplegia. In the five cases which came under the author's observation congenital syphilis was present, and in three there was consanguinity of the parents. From observation of the cerebro spinal fluid in his cases De Stefano concludes that the condition is due to a direct action of the syphilitic virus on the meninges, followed by more or less extensive degeneration of the nervous system. Familial spastic paraplegia, which was first described Strümpell in 1880, is characterized by the association of the familial character of the disease with spastic paralysis, which is almost constantly accompanied by disturbance of the intelligence and often of speech. It is to be distinguished from the spastic tabes dorsalis of Charcot or spastic contracture of the lower limbs in the adult due to primary sclerosis of the pyramidal tracts.

109 Nitro-benzol Poisoning Treated by Blood Transfusion.

HINDÆ NIELSEN (*Ugeskrift for Læger*, September 9th, 1920) considers that the treatment of poisoning with nitro benzol (mono nitro benzol, nitro benzine, oil of Mirbane, $C_6H_5NO_2$) should include transfusion of blood when the symptoms are severe and a fatal issue seems probable. In this connexion he records the case of a servant girl, aged 19, who took a tablespoonful of nitro benzol in the afternoon, vomited soon afterwards, and was admitted to hospital the same evening in a state of delirium and unconsciousness. She was extremely cyanosed, the mucous membranes being of a dark blue colour. There was a bluish froth about her lips, and her breath smelt of oil of bitter almonds. Her stomach was repeatedly washed out, and oxygen was administered, but her condition remained critical. Accordingly, 600 ccm. of her blood were withdrawn, and an intravenous injection of 1 litre of citrated blood (0.4 per cent sodium citrate solution) obtained from a nurse was given. During this procedure the colour of the patient's skin changed to a rosy tinge. Ultimately complete recovery was effected without signs of embolism or thrombosis. With reference to blood transfusion, the author emphasizes the advantages of collecting the blood from the donor in ten separate vessels instead of in one large vessel. In the latter case coagulation in part of the

blood is apt to extend to the whole quantity. But when several vessels are used, coagulation in one does not spoil the results for the remainder; in the author's case coagulation did occur in one, but not in the remaining nine vessels.

110. Smoking and Mental Activity.

BAUMBERGER and MARTIN (*Journ. of Industrial Hygiene*, October, 1920) give a first report concerning the industrial efficiency of persons using tobacco in different amounts. The output curves of a small group of Morse code telegraphic operators were examined; the occupation of these workers demanded concentrated attention and delicate neuro-muscular co-ordination. It was found that the heavy smokers of the group showed a higher output rate at the beginning of the day than the light smokers, but that their rate fell off more markedly in the later hours, and that their production for the day was definitely less than that of the light smokers. The heavy smokers showed also less ability than the light smokers to respond to increasing pressure of work in the late hours of the day by handling their full share of the work presented to them. These results are in accord with the suggestion advanced by other investigators, that strenuous mental work is likely to be affected adversely by heavy smoking.

111. Chrysarobin and Psoriasis.

WARD (*British Journ. of Dermatology*, October, 1920) relates the case of a man, aged 38, who had suffered intermittently from psoriasis since he was 17, in whom a fresh outbreak of psoriasis papules developed as the result of using a chrysarobin ointment twice as strong as usual—10 grains instead of 5 grains. The fresh lesions were successfully treated by application of the milder ointment.

112. Malaria caused by Injection of Human Serum.

VAN DIJK (*Nederl. Tijdschr. v. Geneesk.*, September 25th, 1920) records the case of a nursing sister, suffering from a severe attack of influenza, whom he transfused with the blood of another sister convalescent from the disease. Three weeks later the first patient developed a typical attack of tertian malaria. She had never had a previous attack, and there was no malaria in Rotterdam at the time. It then transpired that the donor had suffered from malaria, though her last attack had occurred seven months previously; malarial parasites were found in her blood.

SURGERY.

113. Detachment Fractures following Strain.

USLAND (*Medicinsk Revue*, August-October, 1920) discusses the mechanism and treatment of detachment fractures caused by sudden violent exertion. One of his patients, aged 17, tried to kick a football with his right foot, but expended much of the force of the kick on the ground. Violent pain was at once felt in the left inguinal region; he collapsed, and could not stand up again. A skiagram showed a detachment fracture of the small trochanter on the left side. He was kept in bed with the left leg raised and immobilized with sandbags for nearly three weeks. Uneventful recovery followed, and a skiagram showed solid bony union. The author records two cases of detachment fracture of the tuberosity of the tibia, one of which was treated by operation (osteosuture with silver wire and chromic acid catgut), the other with plaster-of-Paris immobilization for six weeks. In both cases complete recovery was effected. Reviewing his own experiences and the literature of the subject, the author notes that, as a rule, the symptoms are slight and medical aid is not sought. The patient continues his exercise, sparing the affected limb when it hurts; in the course of about a year spontaneous recovery is complete. When the symptoms are severe enough to lead to a medical examination, a correct diagnosis and proper treatment soon result in complete recovery. The author points out that in the case of the leg it is better to immobilize the limb with plaster-of-Paris for five to six weeks than to neglect immediate adequate treatment, and merely to impose a general interdiction on all exercise for a couple of years.

Pepsin Treatment of Ozaena.

114. DE LEVIE (*Nederl. Tijdschr. v. Geneesk.*, December 18th, 1920) describes Griessmann's treatment of ozaena, which proves very effective owing to its combination of a chemical with a mechanical factor. A powder containing pepsin is insufflated into the nostrils, which are also irrigated with

a solution containing pepsin. The pepsin exercises a digestive action on the nasal crusts, as has also been found *in vitro*. Crust formation no longer takes place; for the pathological secretion combines with the powder before this can occur, and it is thus very easy to clean out the nose by irrigation. Griessmann states that a few days after the use of the powder the crust formation and foetor considerably diminish. De Levie, who employed the method in fifteen cases of ozaena, fully confirms Griessmann's observations, the results being much more satisfactory than those obtained by any other mode of treatment. He modified the original method by using a weak saline solution for nasal irrigation.

115. Acute Necrosis of the Pancreas.

MOCCIA (*Il Policlinico*, Sez. Prat., November 1st, 1920), who records an illustrative case in a woman aged 40, agrees with Mayo-Robson that the symptoms of haemorrhagic pancreatitis are so indefinite as to render the diagnosis impossible. He regards, however, the following symptoms as suggestive: localization of pain and muscular resistance a little above and to the right of the navel; a contrast between the gravity of the general condition and the relatively slight objective signs; intense cyanosis of the face and subnormal temperature, together with induracia and defect of the pancreatic function shown by steatorrhea, glycosuria, and azoturia. A past history of recurrent attacks of epigastric pain with vomiting, icterus, etc., and signs of a tumour between the xiphoid cartilage and the umbilicus makes the diagnosis still more certain.

116. Syphilis of the External Ear.

LUND (*Ugeskrift for Læger*, October 21st, 1920) has observed in a year no fewer than 13 cases of syphilis of the external ear, the disease being secondary in 9 cases and tertiary in 4. He calculates that syphilis of the external ear occurs in about 2 per cent. of all cases of syphilis. As many as 9 of his 13 patients were women, and he notes that this preponderance of females has been observed by other writers, who explain it as the result of wearing long hair over the ears. One of the author's patients illustrated this point well; her hair formed a caked pad covering the ear. With regard to the differential diagnosis, most writers attach importance to enlargement of the adjacent lymphatic glands, but the author could find no great enlargement of the glands in the mastoid, submaxillary, or retromaxillary regions in any of his cases, which showed only slight general polyadenitis. In one case the papular eruption was confined to the external meatus; there was no middle-ear disease, no general secondary eruption, and no marked adenitis; Wassermann's reaction was negative, but syphilis was diagnosed because of the history, the specific appearance of the papules, and the recovery effected by antisyphilitic treatment. The author can find a record of only one similar case; the diagnosis was clinched in this case by the development of a typical secondary eruption a week after the appearance of papules on the ear (Beck, 1911). Syphilis of the external ear being comparatively refractory to general specific treatment, this may have to be supplemented by local application of calomel in the form of a powder, an ointment, or a solution of salvarsan in a compress. Local treatment with silver nitrate or concentrated chromic acid, as recommended in the textbooks, provokes pain without any therapeutic compensation.

117. Varicose Veins Treated by Intravenous Injections of Sodium Bicarbonate.

SICARD and PARAF (*Bull. Soc. Méd. des Hôp. de Paris*, November 18th, 1920), impressed by the results which followed injections of luargol, have treated many cases of varicose veins by intravenous injections of a 10 per cent. solution of sodium bicarbonate. To avoid silica contamination the solution should be sterilized in hard glass. The most important practical detail is to ensure that the solution should go into the vein alone and not the surrounding tissues, otherwise a troublesome slough may follow. The results were very successful, and no embolism, no toxic symptoms, and no widespread thrombosis was ever observed. Injections are given every day or every other day according to the necessities of the case. They are said to be painless, and the treatment requires no laying up, and can be carried out without interfering with the patient's work. After injection a brief cramp is sometimes noted. Varicose ulcers—at any rate, those up to 5-franc piece in size—are very favourably affected, and the cosmetic effect is also satisfactory. Where there is a tendency to relapsing phlebitis injections are contra-indicated. As to the duration of the cure, cases which were injected in 1917 and 1918 still remain satisfactory.

118. Intestinal Obstruction due to Gall Stones.

ACCORDING TO PINARDI (*Il Policlinico*, Sez. Chir., November 15th, 1920), who records two cases, the diagnosis of intestinal obstruction due to gall stones has hardly ever been made before operation, as there are no pathognomonic symptoms. Cholelithiasis fairly frequently causes symptoms of transitory or permanent intestinal obstruction. In some cases there is a dynamic paralytic ileus due to localized or generalized peritonitis following cholelithiasis. More frequently there is a mechanical ileus due to occlusion of the duodenum or colon by peritoneal adhesions or to compression of the intestinal walls by a gall bladder distended by calculi or a mixture of bile and pus. Pinardi, however, does not discuss this form of intestinal obstruction, but only that form due to arrest of gall stones in the lumen of the intestine. This variety of intestinal obstruction, though known for a long time, is relatively infrequent. Among 1,152 cases of intestinal obstruction Leichtenstein found only 20 examples, Gonzales collected only 67 cases from the literature, and among over 400 cases of intestinal obstruction operated on at the Ospedale Maggiore, at Turin, Pinardi found only three cases due to this cause. The condition is most frequently, if not exclusively, found in persons over 40, especially of the female sex. The most frequent site of obstruction is the lower end of the ileum.

119 Treatment of Orchitis in Mumps

IT is asserted by BALENGER and ELDER (*Journ. Amer. Med. Assoc.*, November 6th, 1920) that the present method of treating orchitis caused by mumps is inadequate, as is shown by the large number of atrophied testes observed. The plan which they have adopted is to incise the tunica albuginea and relieve the pressure, and at the same time allow the escape of some of the toxic substances produced by the organisms which cause mumps. This must be done early in the disease before the necrotic process has become established, just as in strangulated hernia the operation should be performed early if resection of the intestine is to be obviated.

120 Long-standing Dislocations of the Hip

BUCHANAN (*Surg., Gyn., and Obstet.*, November, 1920) believes that hip dislocations may be considered old at the end of four weeks, after that time reduction by manipulation is rarely successful, owing to a formation of connective tissue which fills the acetabulum and binds down the head and neck. Reduction by open incision is to be preferred in nearly all cases of old hip luxations, and with modern methods is attended with little danger. Preliminary traction by Buck's extension is of advantage. The replacing of the head after the acetabulum has been emptied and the head and neck have been released is best accomplished by manipulation or the use of levers, these may be combined with traction both by the surgeon's arms and by a band fixed to the patient's thigh and passing round the surgeon's neck and shoulder. In 45 cases reported the result was often ideal, and in 80 per cent. good.

121. Local Anaesthesia for Abdominal Operations

WIDERÖF and BORCHGREVINK (*Norsk Mag. for Lægevid. is* *Læben*, November, 1920) trace in detail the development of local anaesthesia in major operations, pointing out the salient features of the most modern methods. To show the extent to which local has replaced general anaesthesia in abdominal operations, they analyse the material operated on between April 1st, 1919, and April 1st, 1920, at the second Department of Ullevaal Hospital. Here 1,548 operations of all kinds were performed, 28 per cent. under general anaesthesia, 5 per cent. under ether or ethyl chloride partial anaesthesia, 3 per cent. under local anaesthesia plus partial general anaesthesia, 47 per cent. under local anaesthesia, and 17 per cent. without any anaesthesia. In 422 of the 1,548 operations, or 27 per cent. of the total, the operations were laparotomies. Of these, after the exclusion of 251 appendectomies, 67 per cent. were performed under local anaesthesia, supplemented in some cases by a little ether inhalation. The authors discuss separately the operations on the stomach, intestines, biliary organs, and the female reproductive organs, and show that only in 4 out of 28 gastro-enterotomies was general anaesthesia adopted. They also preferred to operate on the biliary organs under local anaesthesia. But most of their 251 appendectomies were performed under general anaesthesia, only 22 being performed under local anaesthesia. Gynaecological intra-peritoneal operations were also usually performed under general anaesthesia, but in two cases ovarian cysts were successfully removed without pain under local anaesthesia only.

OBSTETRICS AND GYNAECOLOGY.**122. Polycystic Ovarian Changes**

AMOR (*Gaceta Medica de Mexico*, April, 1920, and *Journ. Amer. Med. Assoc.*, October 2nd, 1920) emphasizes the clinical distinctions between sclero polycystic ovaritis of gonorrhoeal origin and cystic degeneration of the ovaries of non infectious origin. The former condition, he says, is characterized by rapid development of the sclero-polycystic change, this being accentuated by the premature menopause which is frequently induced, no surgical intervention is of use unless the whole organ is removed or oophorectomy performed. In non infectious cystic degeneration, on the other hand, the condition, which is associated with neuralgic pains, is generally traceable to repeated pelvic congestions and a nervous or gouty diathesis, ovariectomy does not always effect a cure, while relief is often obtained as a result of simple laparotomy, incision of the ovary, stretching of the anus, or section of the sacral sympathetic.

123 An Unusual Mechanism of Labour in Placenta Praevia

KATZ (*Zentralbl. f. Gynäkol.*, October 9th, 1920) records two cases of placenta praevia in which the placenta was expelled before the foetus from the uterus. In the first patient, a 9 para, aged 41, haemorrhage, speedily followed by rupture of the membranes, occurred a week before term, the placenta was almost immediately expelled into the vagina, and its maternal surface presented at the vulva. The foetus, which presented by the breech, was born within a few minutes, enveloped in membranes which were intact save at the point of the original rupture. In the second, a 5 para, aged 30, had at term slight pains and some bleeding, followed three days later by a sharp haemorrhage and on the fourth day by rupture of the membranes. A severe bleeding now occurred, but became suddenly arrested, at the same time the vagina was found to be occupied by placental tissue, above which a knee was palpable. Extraction was performed through the placenta; in this, as in the first case, the subsequent course was satisfactory. Prolapse of the normally placed placenta is very rare, but Simpson in 1871 was able to collect 141 cases of birth of placenta praevia before that of the foetus.

124 Unusual Case of Urethral Stricture

HEINRICHSDORFF (*Zentralbl. f. Gynäkol.*, September 25th, 1920) records the case of a female patient, aged 65, admitted to hospital for retention of urine, due to an almost impermeable urethral stricture. Death took place two days later. At the autopsy the bladder showed great hypertrophy, the ureters and renal pelvis were distended, and there was double pyonephrosis. Serial sections through the stenosed part of the urethra and its internal orifice showed the existence amid thickened scar tissue of a fistulous communication between the bladder and vagina. The author concludes that the original cause lay more probably in obstetric trauma than in a gonococcal peri-urethral abscess.

125. Calcified Tubal Mole

MAXWELL (*Surg., Gyn., and Obstet.*, October, 1920) records the case of a woman, aged 55, in whom laparotomy was performed for carcinoma of the cervix. The left tube was found to end in a calcified spherical mass about 3 cm. in diameter, closely adherent to the omentum. After removal the swelling, which was cut with a saw, was found to consist of a calcified shell about 5 mm. in thickness, containing a semi-translucent jelly-like substance, with a thin, bright yellow layer just inside the capsule. Microscopical examination showed the presence of degenerated chorionic villi and the remains of a decidual reaction. Probably an ampullary pregnancy had been transformed into a tubal mole in which adherence of the omentum had prevented tubal abortion, and which subsequently became calcified. The patient had been sterile for twenty five years; no history pointing to past tubal gestation was elicited.

126. Conjunctival Chancre in a Midwife

GLYRD (*Gaz. des Prat.*, August 1st, 1920) records the case of a healthy midwife in whom a series of conjunctival lesions were not recognized to be those of primary syphilis until thirteen weeks after their appearance. The only possible source of infection is said to have been the projection into the eye of amniotic fluid, this, however, is reckoned never to contain spirochaetes.

127. Threatened Rupture of Uterus in Premature Birth by Transverse Presentation.

WERNER (*Zentralbl. f. Gynäk.*, October 23rd, 1920) alludes to a case, occurring in the Wertheim clinic at Vienna, of rupture of the uterus as a sequel to transverse presentation; labour occurred in the sixth month of gestation, and manipulative treatment was deliberately withheld in the expectation that spontaneous delivery would ensue. Werner records a personal case in which the circumstances were similar, but in which the sudden appearance of signs of impending uterine rupture caused expectant treatment to be abandoned. A primipara of 26, four days after the advent of pains and seventeen hours after rupture of the membranes, was found to have a transverse presentation, with vaginal prolapse of a hand; uterine contractions were strong and frequent, the patient felt well, having a pulse of 102, and foetal heart sounds were present. It was resolved to await spontaneous delivery, but an hour later the pulse increased in frequency to 120, the temperature rose, the uterus became contracted so that the foetal parts were no longer distinguishable, the prolapsed hand became livid and oedematous, and the foetal humerus was found to be fractured. At the same time the foetal heart sounds disappeared and Bandl's retraction ring became palpable; the external os was found to grasp the shoulder very tightly and not to be readily dilatable. Decapitation was performed by means of Franz's instrument, for which the author has a preference. The labour is stated in this case to have been premature, but duration of the pregnancy is not mentioned; the foetus was 35 cm. long and weighed 1,270 grams. The author concludes that in the case of premature labour it is not justifiable, even at the twenty-eighth week, to expect spontaneous expulsion; in such cases there is grave risk of a rupture of the uterus. With regard to the vaginal findings, he quotes a case of distension of the lower uterine segments with unruptured membranes (GOLDNER, *Monatsschr. f. Geburt. u. Gynäk.*, 1904, xviii, 4), and alludes to Murray's case (BRITISH MEDICAL JOURNAL, January 11th, 1902) of rupture of the uterus in the absence of cervical dilatation. On the other hand, spontaneous delivery, as a shoulder presentation, has been described in a child of 8½ lb. at term.

128. Extended Hysterectomy after Radium Treatment of Cancer of the Cervix.

GRAVES (*Amer. Journ. of Obstet. and Gyn.*, November 1920) has operated on a number of cases of cervical cancer (whose operability was near the borderline) within a few days of the application of radium; of such operations, three consecutively were followed by acute post-operative peritonitis, fatal in one case. Since this experience the author has waited before operating for at least three or four weeks after the last radium treatment, as recommended by Wertheim. Several applications of radium were found to be followed in a few weeks by extensive parametrial sclerosis, but a single moderate dose interferes much less with the ease of the operation. In frankly operable cases Graves is not convinced of the value of preoperative treatment by radium.

PATHOLOGY.**129. Amyotonia Congenita.**

HOLMES (*Amer. Journ. of Dis. of Children*, November, 1920) has made full histological studies of the tissues obtained at autopsy in a child suffering from amyotonia congenita (Oppenheim's disease). The spinal cord was relatively large for the age of the child (18 weeks), and the anterior roots were diminished in size as compared with the posterior; there was no naked-eye or microscopic evidence of an inflammatory process, acute or chronic, or of recent degeneration. Myelination was normal, and the cells of Clarke's column were well preserved. In the anterior horn large cells were few, and in part were represented by cells of much smaller size, but similar appearance; cells of the normal size, although infrequent, showed the usual characters. The findings in the muscles were in accord with those made by PEARCE (*Ibid.*) in muscle fragments removed during life from another subject of this disease: areas consisting of bundles of hypertrophied but otherwise normal muscle fibres were mingled with small but otherwise healthy fibres which appeared to represent an imperfect stage of development. There was no evidence of a present or past degenerative process, no increase in connective tissue; there was no replacement of muscle tissue by adipose tissue, and the configuration of the brain was normal. In Holmes's case the microscopic appearances

of the musculature of the diaphragm were normal. In Pearce's paper records are given of five cases of amyotonia congenita: two were twins. Pearce agrees with Hucuekens that clinically there is no sharp differentiation between the Werdnig-Hoffmann and the Oppenheim types of disease. In a subsequent paper (*Ibid.*, December, 1920) Holmes forms the conclusion that Oppenheim's and Werdnig-Hoffmann's diseases are extreme types of the same disorder, and that they are probably both related to the group of myopathies represented by Erb's juvenile form of muscular dystrophy and the hereditary form of Leyden and Moebius.

130. Gastric Papillomatosis.

DU BRAY (*Arch. of Int. Med.*, August 15th, 1920) records an interesting case of the rare adenoma of the stomach. Full notes are given of the clinical condition, on which a diagnosis of gastric carcinoma was founded. At operation the true nature of the neoplasm was suspected, and frozen sections confirmed the benign nature of the condition. The tumour mass, which measured about 4 in. in diameter, was found on the greater curvature, and appeared as closely-packed papillomatous growths thrown into folds, and resembling brain cortex in colour and contour. The individual papillomata traced to their bases appeared to be outgrowths from normal mucosa. Microscopically the sections showed a hypertrophy and papillomatous arrangement of the mucosa. The tubular glands were greatly elongated, with much branching and corkscrew formation. Stroma was minimal in amount, and there was no involvement of the musculature. Such benign tumours are frequently accompanied by no abnormal symptoms, and are mostly discovered *post mortem*.

131. Complement Fixation Reaction in Lupus.

ICHOK, GOLDENBERG, and FRIED (*C. R. Soc. Biologie*, November 6th, 1920), in view of the fact that it is difficult to give an experimental demonstration of the tuberculous nature of lupus, which is due either to the small number of tubercle bacilli contained in the lesion or to an attenuation of the virulence of such bacilli, set themselves to find out if the body of a patient affected with such an attenuated tuberculosis was capable of producing specific antibodies. The presence of such antibodies in lupus has been denied. The authors were fortunate in being able to examine no less than 104 cases of lupus. Using Besredka's antigen—an emulsion of tubercle bacilli grown in Besredka's egg-broth—and the usual complement deviation technique, they found that 69 serums gave a positive reaction (66.4 per cent.), 18 gave a partial reaction (17.3 per cent.), and 17 were negative (16.3 per cent.). Amongst their cases, varying from 10 to 74 years of age, not one presented clinical symptoms of a tuberculous localization other than in the skin. In the great majority of cases the disease had existed for more than ten years, sometimes for thirty to forty years. In spite of the more or less considerable extent of the cutaneous lesion and of its tenacity, the rest of the body always appeared free from tubercle. It may be that the body is somehow vaccinated by the circumscribed attenuated infection. Owing to its power of resisting tuberculous reinfection in the majority of cases, the body of a person with lupus is different from that of the normal unaffected individual, and this is corroborated by the positive sero-diagnostic reaction. It is an open question whether the presence of antibodies is an evidence of a still active focus of tuberculosis or of an active resistance preventing the extension of the tuberculosis to other organs.

132. The Meinicke and Sachs-Georgi Reactions.

HAJOS and MOLNÁR, jun. (*Wien. klin. Woch.*, October 28th, 1920), from a comparative examination of the Wassermann, Meinicke, and Sachs-Georgi reactions in several hundred cases, came to the following conclusions: (1) Meinicke's reaction, and still more so the Sachs-Georgi reaction, is a much simpler method than the Wassermann reaction. (2) The sensitiveness of the Meinicke and Sachs-Georgi reactions is somewhat less than that of the Wassermann reaction. (3) The Meinicke reaction is less specific than the Wassermann reaction, but the specificity of the Sachs-Georgi reaction is equal to that of the Wassermann reaction. (4) The Sachs-Georgi reaction can be employed for examination of the cerebro-spinal fluid, whereas the Meinicke reaction is not available for this purpose. (5) The Wassermann reaction cannot at present be replaced by the other two reactions, but the Sachs-Georgi reaction is a valuable supplement, and should always be carried out at the same time as the Wassermann reaction, as in many syphilitic cases it may give a positive result when the Wassermann reaction fails to do so.

PIONEERS AND EMPIRE BUILDERS: No. 108
FOURTH PERIOD, circa 8000 to 2500 B.C.

THE B. W. & Co. ALL-GLASS ASEPTIC HYPODERMIC SYRINGE

Capacity, 20 mins. or 1 c.c.

Price, with two steel
needles in box, 8/6

Removes every difficulty associated with securing asepsis. Barrel, piston and nozzle are entirely of glass, the working surfaces of which are ground to fit each other with perfect accuracy. The nozzle fits into the barrel by means of a perfect plug joint and takes a needle of the usual pattern. Apart from its passage through the needle the solution comes into contact with glass surfaces only, and the four essential parts of the syringe—piston, barrel, nozzle and needle—are instantly detachable and easily rendered aseptic.

SPECIMENS OF CLOTH WOVEN BY THE EARLIEST PIONEERS OF THE TEXTILE INDUSTRY.—One of the chief activities arising out of the greatest event of the Neolithic epoch—the introduction of agriculture—was weaving, with its allied operations. Spinning and weaving, made possible by the cultivation of flax, were widely carried on in the Lake-Dwellings. These habitations, constructed of wood, were very liable to destruction by fire. It is to such a catastrophe that we owe the beautiful state of preservation of the linen fabrics, here reproduced. The carbonised materials fell into the water below, sank into the mud, were covered by a layer of charcoal, and hundreds of years later were excavated from this bed, which lay beneath several feet of peat. No. 1 illustrates the simplest form of Neolithic weaving. Strands of unworked (i.e. not spun) flax were laid side by side and bound and fastened by similar strands. Once the idea of weaving had entered man's mind many varieties of patterns made of spun flax were invented, down to the very complicated weaving of bast and flax together, exemplified in No. 7. Nos. 4, 5 and 6 were certainly carried out with the aid of mechanical means, though there are no remains to show us what manner of primitive loom the earliest weavers employed. No. 4 is a fringe, and was probably used to decorate garments.

THE THEORY OF DISTURBED REFLEXES IN THE PRODUCTION OF SYMPTOMS OF DISEASE.

BY

SIR JAMES MACKENZIE, M.D., F.R.S., ETC.,
DIRECTOR OF THE ST. ANDREWS CLINICAL INSTITUTE.

WHEN we started the Institute for Clinical Research in St. Andrews we recognized that if success were to attend our efforts we must have a clear comprehension of our object, and a definite idea how that object should be attained. We define our object as the

Prevention of the Diseases that are Common amongst the People.

To understand how disease should be prevented it was necessary to know what are the diseases which are common among the people. On inquiry it was found that, except in a small percentage of cases, this knowledge was nowhere to be obtained.

Here, then, the first step to be taken was to know what the diseases are which we wished to prevent.

The next question was how to proceed to get this knowledge. The great majority of the sick suffered from complaints, and showed signs of ill health, but the disease was unknown. In a few cases the disease could be recognized, because medical knowledge had advanced so far as to

FIG. 1.

FIG. 2.

FIG. 1 represents a disease completely diagnosed, where A is the agent acting injuriously on the tissues and producing reactions or symptoms, which are represented by the circles at the periphery—as typhoid fever, or conjunctivitis due to a foreign body in the eye.

FIG. 2 represents a disease not fully diagnosed, where, while the symptoms are recognized, the injurious agent A has not been recognized, though its nature can be inferred, as in measles.

detect certain signs and symptoms which experience had shown to be due to definite causes. Seeing that the diseases we wished to prevent were for the most part unrecognizable, it would be futile to attempt to prevent them, so that it was manifest an undertaking must start with preliminary inquiry into the nature of the diseases.

Definition of Disease.

In order that our inquiry should be pursued in a logical and systematic manner, we sought to get a clear grasp of what we meant by disease. The definition of an abstract term such as disease would probably be given in different terms, according to the standpoint of the definer. After much consideration and discussion we analysed the phenomena in over 1,000 cases and worked out the following scheme, which revealed the present state of knowledge on the subject, and at the same time afforded a guide for our inquiry.

If we take a simple disease like conjunctivitis, where the cause can be ascertained, we find that the diseased state consists of a foreign body which injuriously affects the tissues, causing certain reactions or symptoms, as pain, lachrymation, redness, blepharospasm. Such a condition may be considered a complete diagnosis and can be represented by the diagram (Fig. 1), where A is the injurious agent and the surrounding circles are the reactions or symptoms.

We found in our inquiry that the complete diagnosis is possible only in a relatively few cases—where the injurious agent has been recognized as due to a foreign body or to a microbe, as in typhoid fever, pneumonia, diphtheria.

In some cases the reactions occur in such definite groups that they can be differentiated, and it can be assumed with

reasonable certainty that the disease is caused also by a microbe which has not yet been identified, as measles, small-pox, rabies, etc. These are represented in Fig. 2, in which the injurious agent is represented by a dotted ring.

There were other cases in which the group of symptoms were also capable of differentiation, but in which the nature of the injurious agent was unknown, or a matter of speculation, as in migraine, epilepsy, diabetes, etc. This is represented in Fig. 3, where a point of interrogation represents the injurious agent.

The bulk of patients suffer from diseases in which, so far, it has been found impossible either to recognize the agent or to arrange the symptoms into groups that permit of their clear differentiation from others that they resemble. The nomenclature of such conditions is usually based on the presence of a dominant symptom or of a number of symptoms associated with some organ, such as anaemia, neuralgia, neurasthenia, debility, disordered action of the heart, indigestion. The knowledge of the disease in those cases may be represented diagrammatically (Fig. 4) as a confused heap of symptoms in which it is not possible to obtain a suggestion as to their relation to a common cause.

To the latter group belong probably all chronic diseases, even though the ill health is definitely due to damaged organs which can be recognized by physical signs—as arterio-sclerosis, chronic heart disease, chronic kidney disease, and even consumption and cancer. The reason for including these is that they are probably secondary diseases, the original cause not being capable of recognition.

FIG. 3.

FIG. 4.

FIG. 3 represents a disease with a well-defined group of symptoms, but where the nature of the agent is not recognized—as migraine, convulsions.

FIG. 4 represents the vast majority of diseases, where a number of unco-ordinated symptoms are present with no recognizable cause.

The Relation of Symptoms to Disease.

This method of looking upon disease reveals not only the state of our knowledge of diagnosis, but gives a guide in research. It shows that disease is only revealed by the symptoms it produces, and that even in the few diseases where the nature of the agent is understood it can only be identified in the human body by its symptoms.

A consideration of the history of the recognizable diseases shows that the first step in research is to recognize the symptoms. The next step is to group them together, so that one group can be clearly differentiated from those that resemble it. By this method the clinical observer differentiates the disease, it may be, without recognizing the cause. Having reached this stage, he can present a clear-cut problem to, for example, the bacteriologist, who may complete the diagnosis by discovering the injurious agent. The symptoms of the majority of diseases have not yet been clearly differentiated, and there is little prospect of progress being made until this has been done.

This brief review of our present knowledge of disease shows that the chief aim of medical science—the prevention of disease—can never be achieved till we are able to recognize the diseases. Where success has been achieved and disease prevented, it was due in the first instance to the recognition of the symptoms. The clinical observer who obtained this knowledge succeeded because the symptoms were striking in character and easily recognized—as by the presence of a rash or eruption or other sign. It is reasonable to conclude that if we had a better understanding of the mechanism by which less obvious symptoms are produced we would get nearer to the detection of the agent producing them. When a person falls ill, the fact is made evident only by the symptoms,

so that the only way in which the disease can be detected is by the recognition of symptoms.

The study of symptoms has been carried on since the dawn of medicine, and from the early days additions have continually been made to their numbers, until to-day the number is so great that no one individual can recognize more than a fraction of them, and methods are ever being invented for the discovery of new symptoms. If our enterprise were but to seek for new symptoms, it would be in vain, for the addition of new symptoms would but add to the confusion of a subject already far too chaotic.

The Evolution of a Science.

All subjects that have attained the position of a science have passed through stages of which the collection of facts was the first. So long as these facts were unco-ordinated their accumulation tended to confusion, and there came to be recognized the need for an ordered arrangement based upon a law of nature.

The history of chemistry is an illustration. The appreciation of Dalton's atomic theory gradually enabled the mass of detail to be classified according to a law of nature. Not only this, but it opened up possibilities and gave guidance to further research, and so enabled the science of chemistry to make remarkable progress.

Symptomatology is in the same confused state as chemistry was before the recognition of the atomic theory; and it calls as urgently for a classification based upon some law of nature that reveals the mechanism of the production of symptoms.

The Classification of Symptoms.

Hitherto there has been no clear conception of the nature of symptoms, and the classifications that have been made have hampered progress and misdirected the course of research. Thus symptoms are usually described from the standpoint of the organ giving rise to them, and specialists devote themselves to the study of the symptoms of individual organs or systems. When a person falls ill nearly every organ of the body may be disturbed, and each specialist has no difficulty in detecting symptoms belonging to his particular branch. In consequence of this we find that confusion of diagnoses which results when a patient consults a number of specialists.

Another source of error arises from the fact that when one organ is diseased its impaired function is revealed not by the organ at fault but by its effects upon the other organs of the body.

It is now many years since I saw the need for a knowledge of the mechanism by which symptoms were produced. I have steadily pursued the subject, and several years ago I dimly recognized that there was some definite law governing this mechanism. I attempted a classification and I was able to group a number of symptoms according to their mechanism, such as a *structural group*, recognized by a physical sign, a *functional group* due to interference with the functions of an organ, and a *reflex group*, due to a peculiar stimulus setting up definite reactions. But there remained a large group, which I recognized somehow or other belonged to the last group, but their mechanism was not clear.

This was the state of knowledge when we began our inquiry. We recognized that it was useless to attempt a research into any particular disease until we had acquired a knowledge of the laws that underlay the production of symptoms, and to that end our chief endeavour was given. We met twice a week; at one meeting we discussed the nature of one particular symptom, and sought for an explanation in the daily routine of examining patients. At the other weekly meeting we discussed in detail the symptoms of individual patients.

The Law Governing the Production of Symptoms.

As time went on we got a better insight into one symptom after another, and we felt we were getting nearer the law of which we were in search, and gradually its recognition dawned upon us. At first we scarcely recognized it when it was put before us because of its extreme simplicity, for we found the law to be that the vast majority of the symptoms of disease are disturbances of normal reflexes.

I know quite well that no one who reads this will accept the present view that this theory will do for clinical medicine what the atomic theory did for chemistry, but

I know equally well that when the method of applying it is understood its significance will be appreciated, and it will have a very far-reaching influence on the progress of medicine.

How the Theory was Discovered.

The discovery of this law is the outcome of a long and painstaking search with a definite object in view.

Shortly after entering general practice, over forty years ago, I was impressed with my ignorance of the diseases from which my patients suffered. In the majority the evidence of ill health was confined to the patient's sensations, which I could not interpret. Realizing this, I resolved to see if I could not improve my knowledge, and began to pay more attention to such signs as I could detect, and the principal sensations of which the patient complained. I had not gone far when I realized that these signs and symptoms were so numerous that I could only hope to investigate a limited number. But even when I had selected a few for particular observation I did not know what method to pursue. On reflection I decided upon concentrating my attention on two aspects: (1) *The mechanism by which a symptom was produced*; and (2) *the bearing the cause of the symptom had on the patient's future*.

Of these aspects the latter is, of course, of the utmost practical value to a doctor, and although under the term "prognosis" it has received perfunctory attention, I found that neither the manner in which the subject should be studied nor the individual whose opportunities fitted him for the task had been realized; but with that I do not deal here.

The study of the mechanism by which symptoms were produced led me into several different fields. There was, for instance, the pulsatile movements in the jugular veins and the liver, the movements of the heart in health and disease, and the mechanism of irregular heart action to be considered. I devoted several years to finding out the mechanism of these signs, and the results were an ample reward for the labour and time spent, and helped to make that revolution which has made of human cardiology a totally different subject from what it was when these researches were begun.

The study of the sensations of the patient was much more difficult. I began with the most clamant of all—pain. Hilton's book on *Rest and Pain* was the farthest step that had been taken, but valuable as it was it did not go to the root of the matter. For some years I made little progress—collecting isolated facts but unable to see any reasonable explanation for their causation. In 1888 Dr. James Ross published his article on referred pain, and I at once recognized that he had provided a hypothesis which not only helped to explain much that was obscure but gave a guide for carrying the subject further. In this paper he stated that pain, when arising in an organ, was felt in two ways—first by a pain in the organ itself, and second by a pain felt in the external body wall at a place remote from the organ. The first of these he called *splanchnic* and the second he called *somatic*.

I had already gone so far in my inquiry that I recognized the significance of his somatic or referred pain, but I was doubtful of his splanchnic, considering that it also was really referred. He used as an illustration the pain of gastric ulcer when limited to the epigastrium as being a splanchnic pain, but when I examined a patient with a gastric ulcer I found that on a deep inspiration, while the stomach descended, the pain remained fixed.

Though suggestive this was far from convincing, and I sought diligently for other signs, and in 1891 I found a sign which threw much light upon the matter. This was finding a large area of hyperalgesia of the skin over the liver in a patient after an attack of gall-stone colic. This led me to seek for cutaneous hyperalgesia in other cases and I soon found that it was of frequent occurrence, particularly in affections of abdominal organs. It required, however, a long training to acquire the skill to detect it in many cases.

Shortly after this another sign was recognized—namely, the contraction of the muscles of the abdominal wall due to disease of an abdominal organ. It had been recognized before, and spoken of as "protective rigidity," but its real nature and significance had never been understood. I watched how portions of the muscle wall of the abdomen would become hard and resistant during the course of a

disease, such as gastric ulcer, appendicitis, gall-stone disease, cholecystitis. I observed it disappear with improvement, until it was not evident, and I could recall it by gently rubbing over it. I noted in patients the sudden contraction of muscle that ensued under certain conditions. Thus, some of my patients described that on the onset of an attack of renal colic the testicle would be dragged up (by contraction of the cremaster muscle).

I described these symptoms of pain and hyperalgesia in consequence of disease of the viscera as a *viscero-sensory reflex*, and the contraction of the muscle as a *viscero-motor reflex*.

There was a large group of symptoms which occurred when patients fell ill from some obscure cause (as infection), such as the feeling of exhaustion, loss of appetite, breathlessness on exertion, palpitation, vomiting, mental depression. These had been vaguely described as toxic symptoms, and I had indeed described them as due to a hypersensitiveness of certain parts of the central nervous system, but I did not clearly realize the mechanism which produced them; this was the stage reached when we started the Clinical Institute, and the matter was summarized in an address I gave on the "Soldier's heart and war neurosis: a study in symptomatology."¹

The Application of the Theory.

In the description of the theory and its application which follows, some simple observations are given to show the manner in which certain reflexes are disturbed; while we have found it already of value in the interpretation of our patients' symptoms, we recognize that there is required a much better knowledge of reflexes before the theory can be used in a systematic manner. The illustrations therefore are merely to indicate how it may become of use.

While the stimulus and response parts of a reflex may often be recognized, the mechanism of that part of the reflex in the central nervous system is not yet quite clear. Consequently the diagrams of this part of the reflex do not pretend to represent the actual mechanism.

In attempting so to explain the theory that symptoms arise from disturbed reflexes as to carry conviction we recognize that we are handicapped in that what we take to be facts may not be accepted as facts by the reader, and it would take up too much space and time to give our reasons. When, for instance, I state that exhaustion of heart muscle produces pain and proceed to develop the argument in which that statement is accepted as a fact, the reader may not accept the statement. The observations on which that statement is based have been carried on for many years, during which patients have been watched and the circumstances provoking the pain have been considered, the gradual progress of the case observed, and the conditions at the *post-mortem* examination carefully noted. Another long series of observations have been made to discover the laws that govern the production of pain in all muscular organs—a research, indeed, in which we are still engaged, and which every day tends to confirm the view advanced here. In like manner, when I take it as a fact that exhaustion is due to a disturbance of a vasomotor reflex, it is not possible to give the long series of observations on which the statement is based.

Until we are able to publish the researches into these and other matters involved in this description, I would ask

the reader to assume that our facts are proven, so that the explanation of this theory may be understood.

FIG. 5.—Diagram of a simple reflex arc. The stimulus affects the receptor A, from which a nerve impulse travels to the central nervous system C, which then sends a response back to the receptor B.

Description of a Reflex Arc.

In the reflex arc we recognize the following parts (Fig. 5).

A. The receptor or place where the reflex is initiated.

An afferent nerve fibre conducts the stimulus to B, the nerve centre. Here the afferent nerve ends in a synapse with one or more nerve cells—the actual number and relationship varying in complexity. The nerve centre in turn sends an efferent fibre to C—the effector or structure, be it muscle or gland or centre of

consciousness, which gives the ultimate response characteristic of the reflex.

The whole of this arc is necessary for the production of a simple reflex. Symptoms, or, in other words, alterations in the reflex, may be referable to causes acting upon any part of the arc, but in practice they are found to be mainly confined to alteration in A, the receptor; B, the nerve centre; or C, the effector.

The Part of the Reflex in Life.

The whole economy of the body is built up of a system of organs whose activities depend on reflexes. A flood of stimuli is continually being poured into the system through the skin and special senses, and each stimulus produces a definite reflex on some part of the body. In the deeper tissues of the body stimuli are continually arising and being sent to different organs, which respond by some modification of their activity.

The sources of stimulation, therefore, arise in every part of the body. Organs that at one time are the source of stimulation become at other times the effectors. Thus, when pain is felt, the source (a part of the reflex) may be the peripheral distribution of any sensory nerve, while the brain is the organ which responds (the C part of the reflex). The different organs of the body during periods of activity and quiescence send out stimuli-producing reflexes which modify the activities of other organs—as the heart when it increases its activity in responding to a call for more blood, or decreases its activity in a cessation of effort.

The interplay of these reflexes results in the harmonious action of the organs of the body which we recognize as "health." The disturbance of one or more of these reflexes results in a disharmony which we recognize as symptoms of disease.

Methods by which Disturbed Reflexes are Produced.

There are two ways in which reflexes may be disturbed:

1. By the nature of the stimulus acting on the A part of the reflex arc, the impulse entering through the nervous system.
2. By altering in a positive or negative sense the receptivity of the B and C parts of the reflex, the agent (chemical or thermic) entering through the blood stream.

Disturbance of Reflexes due to the Stimulus Entering through the Nervous System.

The following observations sufficiently illustrate the mechanism by which this kind of disturbed reflex is produced.

Many years ago I had shown that the only serous membrane in which a sensation of pain could be produced was the visceral layer of the tunica vaginalis.

Observation 1.

Dr. Orr, in tapping a hydrocele, tested this statement and noted the sensitiveness of the parietal and visceral layers of the tunica vaginalis. He found he could scratch the parietal layer and the patient feel nothing, but when he touched the visceral layer with the trocar the patient (1) drew back, (2) felt severe pain, (3) became pale, (4) nauseated, and (5) collapsed.

Observation 2.

A man was seized with an attack of renal colic and suffered violent pain in the left side of the abdomen, with contraction of the muscles. He became pale, and sweat poured out; he vomited, and the pulse became soft, and he felt faint.

In Observation 1 the touching of the visceral layer of the tunica vaginalis was the stimulus at the receptive or A part of the reflex. Then followed a variety of responses or effects on the C part of the reflex: (1) A muscular response in the sudden drawing back of the body; (2) the sensation of pain—the centre of consciousness being the response part of the reflex; (3) pallor—a cardiac reflex—due to a stimulation of the vagus, which also probably caused (4) the nausea, and (5) collapse, due to a vasomotor reaction. In Observation 2 we have a similar series of reflexes, these being in addition, the vasomotor reflex causing the sweating, and the vomiting reflex.

Alteration of the Receptivity of the B and C Parts of the Reflex Arc.

The other method, by altering the B and C portions of the reflex arc, comes about through the circulation in the blood of certain agents which affect parts of the arc in a negative or positive way—that is, either increasing or

diminishing the intensity of the impulses during their passage from *a* to *c*.

The demonstration of the disturbance of the reflexes through the nervous system is readily understood from such observations as 1 and 2. The demonstration of the circulatory—chemical or toxic—influences is not so easy. Perhaps the best way is to consider the effects of certain drugs whose effects have been sufficiently observed.

Observation 3.—The Effect of Atropine.

An individual who receives a certain quantity of atropine may complain of impaired vision and palpitation. When examined he is found to have a dilated pupil and an increased heart rate, which is abnormally increased on effort.

Each of these effects is due to the drug blocking the passage of normal impulses at *c*. The pupil of the eye is maintained in an ever-varying balance between dilatation and contraction, responding with great sensitiveness to the stimulus of light. This is because of two reflexes, one presiding over the dilator muscles of the pupil and the other over the sphincter muscles. The atropine blocks the passage of the normal impulses to the sphincter at *c* and the balance is upset. The heart's activity is regulated in the same way by two sets of nerves, acceleration of rate by the sympathetic, and slowing of rate by the vagus. The heart is like the pupil, ever ready to respond to a demand for more or less blood from the tissues, according to their ever-varying activity. The atropine acts by paralysing the peripheral end of the vagus, or by depressing the *c* end of the reflex arc, and the uncontrolled sympathetic fibres cause the increased rate.

Observation 4.—The Action of Strychnine.

In the reflex action of muscles in causing the movement of a joint there occurs normally at the same time as the contraction of the muscles a relaxation of the opposing muscles. Thus in

FIG. 6.—Diagram of a muscular reflex. The stimulus from *A* passes to *B*, where it affects the nerve cells supplying the muscles *C* and *C'*. In response to the stimulus the muscle at *C* contracts, while the muscle at *C'* relaxes. The signs + and - indicate the different actions.

FIG. 7.—Diagram illustrating the effects of strychnine. The response from the stimulus arising at *A* affects the cells at *B* differently, so that while the muscle at *C* contracts the muscle at *C'* does not relax, but also contracts. This is shown by the - sign in Fig. 6 being now a + sign.

Fig. 6 the stimulus arising at *A*, is diverted at *B* to *C*, which causes a contraction of the muscle, and to *C'*, causing a relaxation of the muscle. These reactions are shown by + and -. The effect of strychnine in producing convulsions is by converting the inhibition of the muscles which takes place in a reflex movement of a joint into a contraction of these muscles, as in Fig. 7, where both reactions are seen, represented by + sign.

This observation shows the influence of an agent modifying the reflex at the *B* portion of the arc, and explains the mechanism of the convulsions in rabies as well as in

strychnine poisoning. It is to be noted that neither the strychnine nor the toxin in rabies can by themselves initiate a stimulus for the production of a reflex—this arises always from some part of the body through the *A* portion of the reflex arc, as at the skin. This fact shows that the drug does not cause convulsions, but only modifies the reflex in such a way that the stimulus from *A* produces the convulsions.

These methods of action probably explain the action of all drugs or toxins which are supposed to act on centres. A great number of drugs are credited with causing vomiting for instance, but the manner in which they act is to render the *B* or *C* portion of the arc more susceptible to a stimulus so that a normal stimulus passing into the nervous system affects certain reflexes which have been rendered unduly sensitive.

The following observation shows how a normal act can affect the reflex at *B* when it is rendered hypersensitive by an agent such as a drug.

Observation 5.

A man with a regular heart, after I had given digitalis, showed irregularities which a graphic record demonstrated to be due to the dropping out of ventricular systoles, the auricular rhythm being unaffected. The digitalis was stopped, and in a few days the heart's rhythm became quite regular, the ventricular systoles having ceased to drop out. Commenting on this fact to the patient, he said he could bring the irregularity back, and I asked him how, and he replied, "By swallowing." I requested him to swallow, which he did, and a ventricular systole dropped out. I took a long tracing, and when he did not swallow the rhythm was regular, but as soon as he swallowed a beat was missed. This was repeated a great number of times. Four days later the heart was quite regular, and swallowing had no effect upon the heart's rate.

Observation 6.

A woman, aged 52, experiences attacks in which she becomes prostrated, suffers severe pain in the head, and vomits. If she lies quite still she does not vomit, but if she is startled by a noise—such as the banging of a door or ringing of a bell—or if she smells tobacco or cooking, vomiting occurs.

In this condition there is manifestly a hypersensitive condition of the *B* part of the reflex arc, but it is to be observed that vomiting occurs from a stimulus from the periphery, just as the convulsion in rabies and strychnine poisoning.

The Added or Reinforced Stimulation.

In the production of reflexes in disease the reflex often takes place with unusual ease or facility, a slight stimulus producing an exaggerated reflex or calling into play an unusual reflex, as in Observation 5. The reason for this is that the disease disturbs some parts of the reflex arc rendering them more or less susceptible to stimulation. This may happen in several ways.

In certain forms of visceral disease certain areas of the skin or other tissues of the external body wall show an increased susceptibility to stimulation. Thus, when pressure is applied to the skin of such a strength that in the unaffected part it produces only the sensation of touch or pressure, it produces in these! a sensation of pain. The explanation of this is that the normal reflex is that already a stimulus is affecting the arc from the diseased organ *A*, and the added stimulus of pressure *A'* is sufficient to produce pain (Fig. 8).

The contraction of the muscles of the abdominal wall in disease of abdominal organs (the "viscero-motor reflex") is but an exaggeration of the normal reflex which maintains the tone of these muscles. If the gradual disappearance of these contractions be observed it will be found to merge into that state of resistance which we recognize as tone in these muscles, so that the contraction in visceral diseases is but an exaggeration of the normal tone.

The increased sensitiveness which is shown by hyperalgesia of the tissues of the external body wall is capable of giving rise to pain from a stimulus reaching the central parts of the arc.

Fig. 8.

an ad
The
(say gastric ulcer, a diseased tooth) keeps up a persistent irritation at *B*, so that a stimulus from *A'* (the skin or other organ) not sufficient to cause pain by itself, affects the irritated cells at *B* and produces pain (see also Observations 5, 6, 7).

Observation 7.

A man with advanced aortic disease suffered from attacks of angina pectoris. He had a diseased tooth, which caused a slight degree of pain. During the attacks of angina pectoris, in addition to the pain in the chest and left arm he had pain along the jaw, but the pain was always most severe around the diseased tooth.

In this instance the diseased tooth kept up a continual irritation of the *A* part of the sensory reflex, and the pain would become more severe when pressure was made on it in chewing, the reflex arc being disturbed by an increase of the stimuli at *A*. During the attacks of angina pectoris a pain was felt along the jaw—where there was already a disturbed reflex—this additional stimulus reaching the arc at *B* produced an increase of the pain, or, in other words an increased response, at *C*.

Observation 8.

A man suffered from jaundice with severe attacks of gall-stone colic for several days. The skin of the upper part of the abdomen on the right side was very tender on pressure (hyperalgesia). The pains suddenly ceased and a gall stone the size of a bean was passed by the bowel. The hyperalgesia of the skin persisted, but he suffered pain over the hyperalgesic region on taking food. When the hyperalgesia disappeared he suffered no pain on taking food.

Here, as in Observation 5, a normal stimulus (resulting from the taking of food) on entrance into the central nervous system affected a hypersensitive part of a reflex.

Balanced Reflexes.

There are a great many different kinds of reflexes, some so obscure that their mechanism is not clear. There is one form which from its simplicity illustrates the theory of disturbed reflexes as the basis of symptoms. This is the kind which might be called balanced reflexes, where two systems of reflexes mutually react. This was seen in the description of the reflex contraction of muscles, when at the same time one set of muscles contracts another set relaxes, where strychnine and the toxins of rabies and of tetanus disturb this balance (Figs. 6 and 7). It is also shown in the pupil, where normally the movements of the pupil are exquisitely balanced by the nerves supplying the dilator and sphincter fibres, and where atropine upsets this balance by paralysing the sphincter fibres. It also occurs in the heart, where the play between the accelerator and depressor nerves of the heart results in the delicate regulation of the heart's activity in response to stimuli from the other organs of the body.

In many illnesses the balanced reflex is upset, so that we find the pulse rate a valuable indication of the patient's state. In most toxic cases the rate is increased, possibly by the excitation of the accelerator (sympathetic) part of the reflex. In some cases the toxin stimulates the depressor part, as in typhoid fever, and the effect upon this part of the balanced reflex is seen in certain diseases where the heart's rate becomes very slow, as in the following observation.

Observation 9.

A man 50 years of age began to suffer from sudden attacks of loss of consciousness of brief duration. His pulse was found to be slow, and records—graphic and electrographic—showed that his ventricle was responding only to every second auricular beat. As this is typical of one kind of an over-action of the vagus, an attempt was made to remove this by atropine, which paralyses the peripheral end of the vagus. A hypodermic injection of one-fiftieth of a grain of atropine was followed in ten minutes by the appearance of more beats, and in thirty-five minutes the ventricle responded to every auricular systole.

In this instance the disturbed reflex was due to an over-action of one part of the balanced reflex (the vagus) and the removal of this over-activity at the c portion of the arc by the atropine restored the heart to its normal rhythm.

An example of the disturbance of the balanced reflex, which not only illustrates the mechanism but throws light on a matter of real importance in practice, is afforded by the variation in the heart rate occasioned by the act of respiration. In differentiating the different forms of heart irregularity I recognized one form common in the young, which I called the youthful type of irregularity, and demonstrated that it was produced by the breathing; the heart increased in rate during inspiration and decreased during expiration. This variation was more marked if the individual breathed slowly and deeply.

On inquiring into the significance of this form of irregularity I found it present in young people in perfect health. I found it disappeared when any febrile illness caused an increase in the heart's rate, and it returned when the fever fell and the rate returned to normal. I have used this irregularity for over twenty years as a guide in doubtful cases after recovery from illness, looking upon its presence as a proof that the disease had departed, and that the heart was free from any active process. This view is now justified. Under ordinary circumstances the balance between the accelerator and depressor nerves is so even that a stimulus such as breathing disturbs the balance. The presence of a toxic agent affects the reflex, causing an increase in the rate, so that the slight stimulation from the act of breathing no longer has any effect, and hence the reappearance of the irregularity at the termination of a febrile illness.

The Disturbed Part of the Response.

The tendency to heart-block by stimulating the vagus (as by the use of digitalis) is more apt to occur when the bundle connecting the auricle and ventricle is damaged, and the question arises, Is the effect at c which produces heart-block due to an increase of the vagal activity or an increased susceptibility of the responding organ—that is, the auriculo-ventricular bundle? That the reflex may be impaired by the diminished susceptibility of the recipient organ at c can be inferred from the following observation:

Observation 10.

A man 68 years of age consulted me because he had found that on making a considerable effort, as running upstairs, his pulse, in place of increasing in rate, fell to nearly one-half its rate. I tested him, and found that this was so; I considered that the bundle which conveys the stimulus from auricle to ventricle was damaged, so that while the damaged bundle could convey a stimulus at the rate of 60 or 70 times a minute, it failed to do so when the rate became higher. Subsequent records, graphic and electrographic, confirmed this view.

In this instance the normal balance of the reflex between the augmenting and inhibiting nerves to the heart is disturbed by the damage to the recipient organ.

Multiple Stimuli and Multiple Responses.

The response at c may be due to stimuli originating at different places and in different ways. Thus an abdominal muscle may contract in response to a stimulus from the brain, or from the skin, or from the movements of respiration, or from the movements of the body, or from a visceral stimulus, as in Observation 2.

A single stimulus can give rise to a number of responses—indeed, most stimuli do: we have seen that a cutaneous reflex giving rise to a movement of a joint does so by the contraction of one group of muscles and the inhibition of another group, while Observations 1 and 2 showed that in response to a stimulus a number of reflexes followed.

Multiple Reflexes.

During ill health the patient may complain of a number of symptoms, and the doctor may detect a number of signs. This is due to the fact that the agent which causes ill health disturbs a great many reflexes. To look at these signs and symptoms, each one recorded as an isolated fact, presents such a confused picture that a coherent description of the patient's condition cannot be given. When the individual reflexes are recognized, then the symptoms can be grouped upon a rational principle.

This plan of analysis can be employed in studying the reflexes produced by the impaired functions of organs, or by the specific reaction to the toxins of disease, as well as to drugs, in the manner already described.

The Disturbed Reflexes due to Organic Disease.

One essential question in cases of diseased organs is their functional efficiency. When all the organs are functioning in a normal manner the reflexes pass unnoticed by the individual. When a failure of function takes place the reflexes are disturbed and symptoms appear. It is difficult to recognize the real source of a reflex, for many organs when they fail to function in a normal fashion do not themselves show the signs of failure, but the signs are shown by other organs that are deprived of the material the erring organ contributes to the economy.

While the failure of each organ will give rise to different reflexes the fundamental principles governing the production of the symptom will be the same.

The Disturbed Reflexes due to Heart Failure.

The symptoms produced by heart failure offer a good illustration, as they have been worked out in some detail.

When a healthy individual engages in violent physical effort he will in time produce exhaustion of the heart, so that it no longer supplies sufficient blood to the organs and tissues, and the individual suffers distress. The same thing happens when an individual with a diseased heart undergoes an effort which leads to exhaustion, only in the second instance the amount of effort is less. The signs of heart failure are those of distress and are not to be found by the examination of the heart but by effects of an insufficient supply of blood to other organs. This is well recognized in advanced heart failure when there are

in addition to distress on effort, the physical signs of dropsy and an enlarged liver.

In the great majority of people who suffer from heart failure these physical signs never appear. In them the heart failure is made manifest by a limitation in their response to effort; they are pulled up by distress in some effort they were wont to perform in comfort. This is because of certain reflexes that are set up by organs which suffer from an insufficient supply of blood. The reflexes are of a nature that produce distress of such a clamant kind that cessation of effort is called for. They are mainly of two kinds—the distress associated with (1) breathlessness and (2) pain in a distinctive region.

In healthy people the most frequent evidence of heart exhaustion (as in running) is breathlessness and the accompanying sensation of tightness at the throat and a sense of suffocation. Occasionally there is also a sensation of constriction of the chest with pain across the chest.

What happens in a healthy person is also what happens in one with a weak and diseased heart, one difference being that less effort produces the distress in the latter case and another that pain is a fairly frequent cause of distress.

The mechanism of these two reflexes is quite distinct. Respiratory distress is the outcome of a disturbance of the respiratory reflex on account of the heart being unable to supply purified blood to some part of the respiratory system. I do not discuss further this mechanism here, as it would lead us too far, but everyone recognizes that breathlessness is a sign of heart exhaustion and that it is due to a disturbed reflex.

The other reflex, of which pain is the dominant feature, is a reflex arising from exhaustion of the heart muscle itself. The pain is often accompanied by other reflex signs, as contraction of the intercostal muscles producing the constriction of the chest—sometimes of such extreme violence as to be more dreaded than the pain. Sometimes the mouth fills with saliva, and the pain may be felt not only in the chest but in the arms and along the jaw (Observation 7). These are multiple reflexes comparable with that described in Observation 2.

Observation 11.

A man 68 years of age complains of breathlessness on going up a hill or stairs. Also of pain across the chest, on effort under certain conditions, such as walking out on a cold day or after a full meal. The pain across the chest is preceded by a sense of tightness, or constriction, such as used to pull him up when running a race in boyhood. These signs of limitation have come on gradually, and he noticed his limitation fifteen years ago. There are no physical signs of disease, except some arterial degeneration.

This account is one common to a great many people, in whom the coronary arteries become diseased so that the heart muscle does not receive an adequate supply of blood.

In this case the heart in supplying the active muscles of the legs fails to supply other parts with enough blood, and amongst others the respiratory system is affected, and gives rise to the complex reflex which is called breathlessness. At other times the heart muscle does not receive a sufficient supply of blood, and it gives rise to its peculiar reflex—pain and contraction of the muscles of the chest wall.

In heart exhaustion, then, we have two prominent reflexes—the one arising from a deficient supply of blood to the respiratory organs, and the other arising from exhaustion of the heart muscle. Which of these reflexes first appears on heart exhaustion depends on whether the respiratory or cardiac reflex is first called into play. In the case quoted, under certain circumstances it was the respiratory, and under others it was pain. Occasionally they may both appear.

In certain cases the respiratory reflex is readily produced, as in auricular fibrillation—a condition in which pain is infrequent and rarely severe, while in diseases which limit the supply of blood to the heart muscles pain is readily induced. In the following instance the reaction of the reflex to the different heart states is brought out.

Observation 12.

A man 66 years of age consulted me for pain on walking. The pain at first was only produced by walking, and only on certain occasions—mostly on walking after a meal. The pain was situated across the chest, and was accompanied by a gripping sensation. As years passed the pain became so easily provoked that walking under any circumstances would cause it. The

heart was normal in size and the rhythm of the heart normal. One day, when 72 years of age, he called to see me, and said that until recently he could walk 200 yards before the pain compelled him to stop. Now he can only walk 100 yards when he is pulled up, not by pain but by breathlessness. Indeed, since this breathlessness occurred he had not suffered from pain. On examination I found the heart was irregular in its action, the irregularity being characteristic of that due to auricular fibrillation.

This is not an isolated instance, as I have had several cases with a somewhat similar history, but explains an observation I made many years ago, that people with auricular fibrillation do not suffer from severe attacks of angina pectoris.

The Effects of Drugs.

It has already been shown that drugs act by causing a disturbance of reflexes. This way of looking at the action of drugs explains much that is obscure in pharmacology, as the following observation shows.

For a long time it was recognized that digitalis acted in a remarkable manner in some cases of rapid pulse in reducing the rate, while it had no effect in other cases. It was never understood why there should be this difference. I found out about fifteen years ago that in the cases in which it had this slowing effect the heart was regulated by abnormal rhythms—mainly that abnormal rhythm due to the condition now recognized as auricular fibrillation. I have attempted many times to reduce the increased rate of the heart when the rhythm was normal, and invariably failed. I speculated for a long time as to the cause of this difference, but never understood it till the theory of disturbed reflexes made the matter plain.

In infectious diseases—as pneumonia, measles, etc.—the balanced reflex that moderates the heart's action is disturbed by the toxins of the causal agent of disease, so that the rate of the whole heart is increased.

In auricular fibrillation this reflex is not disturbed. When the rhythm is normal the ventricle contracts only to the stimulus that arises from an auricular systole. In auricular fibrillation there is no rhythmic contraction of the auricle, but a continuous fibrillary twitching of the muscle, so that in place of the regular stimulus from the contracting auricle there is a shower of weak stimuli which assail the conducting system between auricle and ventricle, and cause the rapid ventricular rate. Not only is there this difference in the cause of the increased rate, but there is a difference in the condition of the cardiac reflex. In rapid pulse with the normal rhythm the reflex is disturbed by the toxins of the diseased state, so that the digitalis can produce no effect. In auricular fibrillation the reflex is unaffected, so that the digitalis can act upon the vagus portion, and in doing so depresses the conducting mechanism to the ventricle and renders it not so susceptible to the numerous stimuli from the auricle.

The Analysis of Symptoms.

In many diseases all the symptoms on which a diagnosis is based are reflex in origin—in some the reflexes are disturbed by the entrance of the stimulus through the nervous system, and in others the disturbance is through the circulation. To the former belong the symptoms of such diseases as gastric ulcer, renal calculus, gall-stone disease, where the symptoms are of the type described in Observation 2. The symptoms in infections are due to the disturbance of the reflexes through the circulation, as influenza, malaria, typhoid and typhus fevers, measles, and abscess formation, apart from the swelling.

In some diseases we get a mixture of both kinds of reflexes, as in appendicitis, where there is not only the local pain and tenderness of the tissues of the external body wall, with contraction of the muscles of the abdomen, but the feeling of exhaustion, rapid pulse, tendency to vomit. In cholecystitis we get a similar complex.

The need for the more accurate recognition of symptoms is seen when it is considered how difficult it is to diagnose even such seemingly simple affections as gastric ulcer and appendicitis. Though surgeons have been operating for these complaints for many years, the most experienced recognize that in many cases they find they have been mistaken in their diagnosis. This is due in a great measure to the fact that the nature and mechanism of the symptoms of these diseases have never been understood, and the symptoms were never clearly differentiated from those of other diseases which they resemble.

It will thus be seen that symptomatology is like chemistry, where the combination of elements results in the production of a great number of compounds bewildering in their variety. Nevertheless, as in chemistry, when they are subjected to strict analysis they can be resolved into their component elements. When the analysis of symptoms is studied as fully as the analysis of chemical compounds have been studied, then it will be possible to group the disturbed reflexes in an orderly manner. The next step then will be to find out the agents capable of provoking the different reflexes, so that we get nearer to the immediate cause of disease.

The employment of this method of investigation is but a return to those methods of clinical research which were so fruitful in their results in the past, especially during the early half of the nineteenth century. To realize how great the progress was during that period we have to consider the discoveries associated with the names of Addison, Bright, Graves, Adams, Stokes, Cheyne, Paget, Hodgkin, and Jenner. These observers employed the most useful of all weapons in research—the trained senses. What we aim at is to recognize the methods which these great observers employed, and by improving and refining their methods restore clinical medicine to the van of research.

Structural and Functional Symptoms.

A certain number of symptoms are due to structural changes and functional derangements. These are generally shown by physical signs, and are due to departures from the normal in various ways, as in alteration in the size and shape and consistence of organs, changes in the colour, as pallor, modification of the sounds of the heart and lungs. These are not dealt with here, but will have to be reconsidered in view of this theory of disturbed reflexes, because many apparently structural and functional signs are really disturbed reflexes, or are produced by disturbed reflexes.

A Preliminary Note

ON

THE HISTO-PATHOLOGY OF EPIDEMIC (LETHARGIC) ENCEPHALITIS.

(With Special Plate.)

BY

C. DA FANO, M.D.,

LECTURER IN HISTOLOGY.

(From the Physiological Laboratory of King's College,
University of London.)

INTRODUCTORY.

In a previous communication on the same subject published in collaboration with Miss Helen Ingleby, M.B., mention was made of a granular, pigment-like material occurring in the nerve cells of regions of the central nervous system where brown or black pigment is not usually found. It was also pointed out that in certain nerve cells small round or oval bodies had been detected, in the middle of which a granule could be seen. The optical impression of such an appearance, when present in Bielschowsky or Nissl preparations, was that of a sort of whitish halo surrounding each granule.

When that note was written no more detailed description of these pictures was given, both because it was meant to be only a short comment on a demonstration of preparations and because I was still uncertain as to the significance of such appearances. It was only later on that a careful examination of a great number of specimens convinced me that I had under observation something not, as far as I knew, hitherto described either in epidemic encephalitis or in other diseases of the central nervous system. As, however, the doubt of an optical illusion could not be entirely dispelled, no further communication was made on the subject, and I waited for an opportunity of somehow strengthening my conviction. This presented itself under the form of a few preparations I was able to obtain recently in Paris through the kindness of Dr. H. Durand, Chef de laboratoire of Professor Netter of the Hôpital Trousseau, and of Dr. Trétiakoff, Chef de laboratoire of Professor P. Marie at La Salpêtrière.

Though many of my doubts are still present, the new

facts observed are, in my opinion, such as to require control from those interested in the pathology of epidemic encephalitis. I propose, therefore, to give now a brief description of the already mentioned appearances and of the more recently observed facts, reserving any further discussion about the occurrence of the granular, pigment-like material for another paper.

FIRST HISTO-PATHOLOGICAL FINDINGS.

A fairly good idea of the appearances to be described is given by Fig. 1 (special plate), which is a photographic reproduction of a coloured drawing† made from a toluidine blue preparation of material fixed in alcohol and embedded in celloidin.

This large nerve cell was seen in the lower part of the medulla oblongata, near the middle line, a little ventrally to the nucleus of the hypoglossus, of the first case of epidemic encephalitis published in collaboration with H. Ingleby. As clearly shown in the figure, the Nissl substance has undergone an almost complete process of chromatolysis, all that remains of it being still visible at the edges of the cytoplasm and near the nucleus, which, though retaining its form, has become shifted to the periphery of the cell body. The whole of the cell body is beset with a great number of granules easily distinguished in the preparation because of their blue stain contrasting with the purple of the fundamental cytoplasmic framework. The granules are found in the deep as well as in the superficial parts of the cytoplasm, and nearly all of them are surrounded by a minute light area which under moderate magnification looks like a halo, but under very high power and proper illumination appears as a very delicate, though sufficiently well defined, body, whitish or slightly bluish in colour, and irregularly round or oval in form. As a rule there is one granule in each body, though in some of them two granules, arranged like diplococci, can be observed. Most of the bodies are discrete, and only a few appear united in dumbbell-shaped forms. The granules measure about $0.4\ \mu$, their surrounding light areas from 1.4 to $1.8\ \mu$ in diameter.

These are the appearances which repeatedly attracted my attention. For the sake of brevity they will henceforth be spoken of as "minute bodies," comprising in this term also the granules which appear to occupy their centre. It must be pointed out here that specimens as plain as that shown in Fig. 1 are very rare. In most instances the "bodies" are seen in altered nerve cells, together with a variable quantity of granular material which becomes stained by toluidine and polychrome-methylene blue in various shades of green. This is mentioned both because it may help other investigators in their search for the "bodies," and because it shows that their recognition is not hampered by the presence, within the nerve cells, of a granular material with which they seem, however, to have some relation.

A good instance of this is given in Figs. 2 and 3, which are likewise photographic reproductions of coloured drawings, the former being made from a toluidine blue, the latter from a polychrome-methylene blue preparation. The large nerve cell shown in Fig. 2 was found in the reticular formation of another section of the same medulla oblongata from which Fig. 1 was drawn. The diseased condition of the cell is clearly proved by the advanced chromatolysis, deformation, and peripheral shifting of the rather opaque and dark nucleus. The middle parts of the cytoplasm are occupied by a number of granules which in the preparation were stained a yellowish-green. Some of them appear here and there surrounded by a very small light area which, up to a point, imparts to them an aspect similar to that of the "minute bodies" which are particularly noticeable in the peripheral portions of the cytoplasm. These do not differ as regards form, staining properties, and situation, from those shown in Fig. 1. Outside the nerve cell two other "bodies," identical with those situated within it, can be recognized on the top of small fragments of protoplasmic material the exact nature of which could not be ascertained. In the same Fig. 2 another nerve cell has been drawn, showing for the purpose of comparison a common process of vacuolization.

The two nerve cells shown in Fig. 3 were drawn from the layer of small pyramids of a section of the first frontal

† Towards the expenses of this research a grant was made by the British Medical Association.

† All figures illustrating this paper were drawn by Mr. W. Pilgrim with the help of the Abbe-Zeiss camera lucida, comp. oc. 8 E, obj. 2 mm. Z., drawing sheet at the level of the microscopic table.

convolution from the alcohol material of the second case of encephalitis published in collaboration with H. Ingleby. Both of them have undergone a more or less advanced process of vacuolization, the vacuoles having been probably occupied by some fatty-like material dissolved by the alcohol fixation and successive treatment for embedding in celloidin. In the smaller cell a few typical "minute bodies" can be seen; in the larger one it is easy to recognize, beside the "bodies," small clumps of a granular material, stained a dark green in the preparation, and also surrounded by a light area similar to that which characterizes the typical "bodies."

FRESH EVIDENCE.

Investigations had reached this stage, but no further progress had been possible, particularly because all attempts to obtain a differential or at least more defined stain of the "bodies" had failed to give satisfactory results. The same can be said of the method commonly used for staining bacteria, their spores and capsules. The question was therefore left in abeyance until the opportunity arose of meeting Netter in Paris. During the conversation we had on the subject the following points were particularly emphasized by him: (1) The similarity existing in certain respects between epidemic encephalitis and certain forms of sleeping sickness on the one hand and rabies on the other. (2) The involvement in almost all cases of epidemic encephalitis of the salivary glands, a fact which he and Dr. Durand could support both from clinical and histo-pathological points of view. (3) His conviction that the direct etiological factor of the disease ought to be looked for in some agent similar if not akin to the Negri bodies.*

Of the preparations shown to me by Durand some were of nervous tissue, and on looking at them I had the rather vague impression of seeing within the nerve cells bodies which reminded me of those seen in my own preparations. Other specimens were from a salivary gland of an acute case of the disease, and these clearly showed in the interstitial tissue zones of small-celled infiltration very similar to that one meets with in the nervous tissue from cases of epidemic encephalitis.

As I was much interested in such an observation Durand presented me with two slides, on each of which were stuck three unstained paraffin sections of this salivary gland. When back in my laboratory the slides were cut in such a way as to obtain six separate preparations, which I stained with toluidine blue, polychrome-methylene blue, Weigert's iron haematoxylin, haematoxylin and eosin. In the areas of small-celled infiltration of three of them "minute bodies" were found similar to those detected by me in the central nervous system. The granules were stained either blue or blue black according to the method used; their surrounding areas had again the same whitish or slightly bluish appearance as above.

As seen in Figs. 4 and 5 the dimensions only of some of the central granules are somewhat larger than those of the granules noticeable in most of the "bodies" seen both in these specimens and in the nervous tissue. This difference has been a little emphasized in the photographic reproductions illustrating this paper by the fact that Figs. 1 and 2 have had to be reduced by two-tenths, while all others are of the same size as the original drawings. It is interesting to note that some "bodies" are situated within the cytoplasm of the infiltration cells while others lie free in the tissue, or, as in the case of the two extracellular forms shown in Figs. 2 and 5, they appear situated on the top of or attached to some protoplasmic material of not quite definite nature.

The purpose of my visit to La Salpêtrière was to see the preparations of epidemic encephalitis of Marie and Trétiakoff, but particularly "les volumineuses granulations entourées chacune d'un halo clair" described by them in the nerve cells of the substantia nigra, as well as the "inclusions homogènes dans le protoplasma de volumineuses cellules nerveuses du Noyau Rouge," also observed by them in their case No. 3. It is outside the province of this paper to enter into a discussion of the significance of these inclusions, particularly of the "volumineuses granulations," considered by the authors as a phenomenon "analogue à celui décrit par Alzheimer sous le nom de dégénérescence graisseuse à gros grains,"

but it should be noted that the fact corresponds to the description given by the authors, though the explanation might perhaps be different.

At La Salpêtrière both Trétiakoff and I looked for the "bodies" in the preparations kindly shown to me by him; but as nothing clear could then be found he gave me the following polychrome-methylene blue specimens for further investigation: (1) A normal preparation of the mid-brain of an individual of about 40 years of age; (2) two sections—one of the optic thalamus and one of the mid-brain—of a case (Shibler) who had died in consequence of a relapse of the malady; (3) one section of the optic thalamus of an acute case (Baudeloque).

In the normal preparation, just as in my own control specimens, I failed to find anything resembling the "bodies." The section of the optic thalamus of the case Shibler was spoiled on the journey, and no use could be made of it; but in the grey matter surrounding the Sylvian aqueduct of the mid-brain section of the same case a few nerve cells were found the protoplasm of which was beset with small clumps of granular, pigment-like material. These had stained a yellowish-green and could be distinguished with sufficient ease from a few "minute bodies" identical with those seen in my own specimens. The preparation of optic thalamus of the acute case (Baudeloque) was also damaged during the journey, but it could be dismounted and restained with toluidine blue. In this specimen, in which the small-celled infiltration was of extreme intensity, neither pigment-like material nor blue granules could be found within the nerve cells, but "bodies" similar to those observed in the salivary gland were seen scattered in the nervous tissue, particularly near areas of perivascular infiltration (Fig. 7). In a few places forms occurred of which the central particle appeared to consist of two granules arranged in pairs as described above, but in this case one only of them was stained blue, while the other had taken a metachromatically red tinge. In regard to the peculiar tetragonal form shown in the same figure and consisting of two relatively larger purple-red and two relatively smaller blue granules, I think it advisable for the time being to reserve any judgement.

GENERAL CONSIDERATIONS.

It is evident that the possible value of my observations is, in great part, connected with the fact that they were made on varied material from different cases. Indeed, it is only the knowledge of the presence of the "minute bodies" within the nerve cells that has made it possible to recognize them outside the nerve cells in the nervous tissue, as well as within and without the cells forming the small-celled infiltration of the salivary gland specimens. On the other hand, this last observation, which by itself would be worthless, has given to my old finding a fresh significance. Of course, the possibility remains that the "bodies" seen in my specimens and in those for which I am indebted to Dr. Durand and Dr. Trétiakoff might be different, in spite of the similarity in aspect and staining properties. But if so, two different suggestions ought to be put forward to explain the presence of peculiar "bodies" in tissues more or less affected by the same disease. And this seems to me the chief point to be borne in mind: the pathological process underlying these observations being the same, so ought their explanation to be.

With this object in view the following three suggestions seem to me worth briefly considering: (1) That the bodies are the result of an optical illusion; (2) that the granules alone are either bacteria or products of a cell degeneration, their bluish or whitish haloes being again an illusion produced either by light or by vacuolization; (3) that the "bodies" are appearances directly due to the presence in the tissues of an agent, cause of the disease.

As to the first supposition, it has already been said how and why it has been the cause of considerably delaying the publication of this paper. However, I wish to point out here and now that such a suggestion could explain perhaps some of my recent observations and the bluish areas surrounding each granule in evidently diseased nerve cells. But this, in any case, only up to a point, as neither pigmented nor vacuolized nerve cells in normal or pathological conditions ever give such a complete illusion, even if highly magnified and looked at by very powerful artificial light. Moreover, some other suggestion ought to be put forward to explain the occurrence within nerve cells of granules which, according to their staining properties,

* Professor Netter and Dr. Durand have kindly consented to the publication of the above statement.

are to be considered as formed either by chromatin or by a similar material.

This takes us to the second supposition, about which, besides some of the reasons just mentioned, I think it useful to remark that bacteriological investigations have been attended, for the present, by negative results, and that, as far as I know, no nerve-cell degeneration has been described resembling the appearances shown in my Figs. 1, 2, 3, and 6.

As to the third hypothesis, I wish to point out that it would link up one with the other the various findings as well as these with histo-pathological changes, which most authors consider extremely like those seen in cases of trypanosomiasis. Those who recollect the aspect of some of the small (internal) forms out of which the Negri bodies appear to result will recognize that between these and the "minute bodies" described in this paper there is a morphological and structural similarity which is at least striking. I quite realize that such a suggestion will acquire value only if other investigators are able to confirm my observations, and particularly if the apparent "bodies" can be found in the nervous or other tissues of animals to which the disease has been successfully transmitted.

SUMMARY.

In the nervous tissue from cases of epidemic (lethargic) encephalitis within and without the nerve cells minute forms have been observed, to all appearance consisting of a central generally basophil particle and of a delicate little stainable body, irregularly round or oval in shape. For these forms the term "minute bodies" is *pro tempore* proposed.

The bodies are generally discrete, and provided with one granule, but dumbbell-shaped forms occur as well as others with two central particles arranged in pairs. An as yet not quite definable relation seems to exist between these forms and a granular, pigment-like material occurring within the nerve cells in places where brown or black pigment is not generally found.

Minute forms, similar in shape, structure, and staining properties to those observed in the nervous tissue, have been traced within and without the cells infiltrating a salivary gland from an acute case of the disease.

After discussing the supposition that such findings might be the product of an optical illusion, associated perhaps with degenerative changes caused by the malady, the suggestion is tentatively put forward that they may be due to the presence in the tissues of a living agent, cause of the disease.

"HARLEQUIN" FOETUS" (HYPERKERATOSIS CONGENITALIS).

BY

JAMES T. MCAUSLAN, F.R.C.S.,

SENIOR RESIDENT SURGEON, ROYAL MATERNITY HOSPITAL,
EDINBURGH.

(With Special Plate.)

The comparative rarity of this condition appears to warrant the following case being reported; only one case has been recorded here in fifty years.

The mother of the foetus was a girl of 16 years, admitted in labour. On vaginal examination, a breech presentation could be made out, but it was obvious one was dealing with an unusual case. The os was well dilated and the skin of the foetal buttocks had the feel of "crocodile skin." One could not employ a more apt term to describe this, as the hard thickened skin was broken up into numerous irregular patches similar to that of crocodile hide.

The full-time foetus was born dead and weighed 7 lb. It presented a¹ s the photographs show. The skin was cornified and cracked in all direction appear as if clad in a horny armour. The distribution of these changes was universal. When a portion of the hardened skin was removed a red raw-looking area was exposed underneath.

The appearance of the eyes was interesting: no differentiation into the various parts, iris, pupil, etc., could be made out, the eyes appearing as two sacs filled with blood.

An examination was made by Dr. F. J. Browne (Assistant Physician, Ante-natal Department), who was unable to make out any definite morbid changes in the internal organs, except in the thymus, which, although of normal size, contained numerous small scatter No spirochaetes could be thymus was suggestive were, I regret, not a success, owing to post-mortem changes. A Wassermann test in the mother, who made an uneventful recovery, yielded a negative result.

This condition has been confused with congenital ichthyosis, but "it is distinguished from it by the fact that it is present at birth, whereas ichthyosis appears towards the end of the first year of life; and by its distribution, which is universal, whereas ichthyosis is rarely very widespread at first, and hardly ever affects the palms and soles, which this disease always does" (Norman Walker).

I am indebted to Dr. Haig Ferguson for permission to publish this case.

ROTATION-DISLOCATION OF THE ASTRAGALUS.

BY

ROBERT OLLERENSHAW, M.D., F.R.C.S.ENG.,

HONORARY SURGEON IN CHARGE OF ORTHOPAEDIC DEPARTMENT,
SALFORD ROYAL HOSPITAL.

(With Special Plate.)

DISLOCATION of the astragalus alone is not a very common accident. The usual displacement is of the astragalus forwards—a condition which often results in a compound dislocation.

A more uncommon displacement is of the astragalus backwards, in which event it is to be felt lying between the tendo Achillis and the malleoli. Dislocation of the bone by rotation in its bed is rare, and when it does occur it is not possible to effect a reduction by manipulative measures. In this form of dislocation the astragalus is frequently detached from all its ligaments. Open operation is necessary, and removal of the astragalus has been the general procedure in the recorded cases. Stimson,¹ in his well-known book, describes dislocation by rotation of the astragalus and refers to seven cases. He insists that the description should only include those cases in which the astragalus has undergone rotation round a vertical or an antero-posterior axis, but still remains mainly within the tibio-fibular mortise. Barwell² reports a case in which he removed the astragalus and where good function was obtained. He recommends primary removal of the astragalus in all cases of rotation-dislocation in which "certain and sufficient, but not too persevering, attempts at reduction" have failed.

For this reason the present case, in which a rotation-dislocation with complete tearing of all ligaments was operated upon and completely reduced with an ultimate restoration of full function, appears to be a circumstance which it is essential to record in some detail.

W. W., male, aged 42 years, was working at the Manchester Ship Canal Docks on May 20th, 1920, and whilst walking with the right foot well advanced a heavy piece of timber fell from a height and struck the back of his left heel. He was admitted to the Orthopaedic Department of Salford Royal Hospital on the same day.

On examination there was an obvious dislocation of the astragalus, the upper articular surface being palpable below the skin on the outer aspect of the dorsum of the foot. There was also a fracture of the fibula two inches above the tip of the malleolus. X-ray examination showed the nature of the dislocation to be a rotation of 90 degrees round the vertical axis (Figs. 1 and 2).

Manipulation was entirely unsuccessful, and operation was decided upon with the idea that astragalectomy would probably be required.

Operation.

A curved incision was made from a point one and a half inches above and behind the outer malleolus curving across the prominence of the astragalus to the mid-line of the foot. The upper and outer surfaces of the astragalus were exposed lying immediately under the skin, and the tendon

of the peroneus tertius, almost completely frayed through. was found crossing the wound. This tendon was retracted inwards, and it was then found that the astragalus was completely free from all its attachments, the posterior surface pointing directly outwards and the head inwards. By forcing the foot into an exaggerated varus position and turning the bone it was possible to replace it so that it occupied its normal position. The foot was then everted, and the torn dorsal ligaments repaired and the peroneus tertius tendon sutured. The fibula fracture was positioned and the wound closed by interrupted sutures, and splinted on a metal shoe with a rectangular foot-piece.

Gentle effleurage was commenced a fortnight later with active flexion and extension of the ankle under supervision to ensure that no inversion of the foot should occur. In the intervals of treatment the foot was retained in the splint. At the end of this time (six weeks after operation) there was very useful movement. Weight bearing was not permitted until three months had elapsed from the date of the injury. Since that time the man has walked comfortably on the foot.

Fig. 3 shows the lateral view after reduction of the dislocation. Figs. 4 and 5 show the range of ankle movement. This case has been very instructive because it shows that removal of the astragalus is not essential, and that excellent function with no shortening—a result much superior to that obtained after astragalectomy—may be obtained by this more conservative method.

ON THE PROBABLE IDENTITY OF RICKETTSIA PEDICULI WITH RICKETTSIA QUINTANA.

BY

A. BACOT, F.E.S.,

ENTOMOLOGIST TO THE LISTER INSTITUTE OF PREVENTIVE MEDICINE.

MUNK and da Rocha-Lima (1917)¹ and Brumpt (1918)² found rickettsia bodies in lice taken from "healthy persons"; the two former writers named this supposed distinct species found by them *Rickettsia pediculi*, although they stated that it was indistinguishable morphologically and in its distribution in the louse from *R. quintana*, which they found associated with lice that had fed on trench fever patients. They infer that there is a form of rickettsia, infecting the gut of lice, which has no relation to trench or typhus fever. If this is correct, the discovery of these organisms in the lumen of the gut has no necessary significance. My colleague, Dr. Arkwright, and myself have, however, examined numbers of lice taken from civilian clothing in London and have never seen rickettsia bodies except when the insects have fed upon patients who have suffered from trench fever, and it is accordingly conceivable that this disease may have existed unrecognized among the population from which Munk and da Rocha-Lima and Brumpt obtained their lice.

The following account of a case of trench fever occurring in a region where the disease was supposed to be nonexistent, in which the rickettsia bodies appeared in lice shortly after the insects were fed upon the patient, is of interest in this respect.

In April, 1920, I experienced while in Warsaw a febrile attack which exhibited the clinical signs of trench fever. The clinical evidence was, moreover, supported by the development of rickettsia bodies in the lice which I took to Poland with me. All the details of the case were under the observation of Professor Wolbach of Harvard, and Professor J. L. Todd³ of McGill, who agreed (1920) that the symptoms were those of trench fever.

On February 18th I joined Professors Wolbach and Todd in Paris in the capacity of Entomologist to the Typhus Research Commission to Poland of the League of Red Cross Societies. I carried with me stocks of *Pediculus humanus (capitis and corporis)* which have been under observation and fed only upon myself since November, 1915. Lice from these stocks were used for experimental work in connexion with trench fever by Sundell and Nankivell, in connexion with trench fever by Sundell and Nankivell, the War Office Trench Fever Committee, and the American Red Cross Trench Fever Committee. Since the com-

mencement of the use of these stocks for trench fever research (more than two years ago) lice from them have been frequently tested for the presence of rickettsia bodies, but the insects have remained free; and prior to my visit to Warsaw I had never experienced any febrile attack which displayed the clinical signs of this disease.

We arrived at Warsaw on February 25th, but owing to unavoidable delays were unable to commence laboratory work until the latter end of March, when, as a preliminary step to the use of our stocks of lice for typhus research, a series of control smears were made from the guts and excreta of lice taken from the boxes. Both the American and English stocks were found free of rickettsia bodies. Steps were next taken to obtain a supply of normal Polish lice for comparison. These we were able to obtain by the courtesy of the officials at one of the municipal bath houses where uncleanly and frequently verminous, but not sick, persons were sent for cleansing, their clothing being subjected to hot-air treatment while they bathed. We were informed that lice from this source would be free from suspicion with regard to typhus.

I searched underclothing for lice in this establishment on March 31st and obtained a small supply, larger numbers being forwarded to us a day or two later by the officials in charge of the bath house. The dissection and making of smear preparations of these Polish lice occupied a portion of my time daily up to April 5th, when the few remaining alive were killed and fixed for sectioning. Of course no attempt was made to feed them. Of 151 of these lice 11 (about 7 per cent.) were found to be infected with rickettsia bodies indistinguishable from *R. quintana*. In sections these were seen only in the lumen of the gut; with smears it is not possible to decide definitely whether the cells lining the gut are or are not infected.

History of Author's Illness.

On April 17th I experienced a sharp febrile attack. Feeling very unwell when I awoke at 6.30 a.m., I took my temperature and found it to be only 97° F., but by 2 p.m. it had risen to 101.7° F. I had a severe frontal headache, and by 9 p.m. my temperature was 103.6° F. I passed a restless night with broken slumber. On April 18th at 8 a.m. the temperature was 101.6° F., and at 10 a.m. 102.3° F., and arrangements were made for me to go to the American Red Cross hospital at Praga. When I arrived there at 3 p.m. my temperature was 101.4° F., at 6 p.m. 101.3°, and at 8 p.m. 101° F. That night I had but little sleep as I suffered from continuous pains in my bones and joints, from ankles to hips and wrists to elbows, accompanied by heavy sweating. These pains, though of low intensity, were, no doubt on account of their wide area of distribution, peculiarly discomforting. On April 19th my temperature remained at or below normal all day. I felt better, but was somewhat depressed and the sweating continued. At night the pains in my limbs were very acute and continued until about 2 a.m., when they gradually subsided and were replaced by a dull confused sensation in the head accompanied by visual hallucinations whenever I closed my eyes. I sweated heavily and got no sleep until after daybreak. I recognized shin pains as more intense than the general aching of my limbs on this occasion. On April 20th I was better in all respects but very weak. My temperature remained down, and at night the limb pains were slight and discontinuous; the shin pains were, however, more intense by comparison. I slept much better.

In view of the possibility of the attack being typhus (I had been dissecting typhus-infected lice twelve days previously), I refrained from feeding my large stocks of lice at the commencement of the attack, but recommended to do so when my temperature fell to normal on April 19th as I was convinced that I had not suffered from typhus.

I was very much better on April 21st, and was told that I might leave the hospital on the morrow, but actually left the same afternoon at my own request, as I was very anxious to get back to my quarters in proximity to the laboratory. I suspected that the attack was trench fever and it was important, in order to settle this point, to keep my stocks of lice in the incubator, and make smears of the lice and their excreta from day to day.

That same night (April 21st) I had a renewal of the attack: temperature up to 101° F., with some increase in the intensity of the pains in limbs, but not sufficient to disturb my sleep. The shin pains were again more intense than those in the other bones, and with each recurrence this feature became more apparent. A noticeable feature in connexion with these pains was that, whereas in the primary attack they did not commence until the fever was subsiding and were still acute after it had left me, they now accompanied the febrile wave. Later they commenced prior to a rise in temperature however slight, and on at least one occasion they occurred without any perceptible rise in temperature. Following this renewal of the attack, my temperature rose each night and fell by day for about ten days, and subsequently became less and less some being. The fever wave tended to increase as the fever waves became less pronounced. Slight shivering, alternating with flushing and followed by sweating, frequently accompanied the slightest rise

indicates opportunities afforded for the lice to feed. +, ++, +++, indicates the presence of rickettsia bodies in the excreta of the lice and the extent of the infection.

of temperature above normal. Shin and bone pains (chiefly in the knees) were often intense, sometimes accompanied by nausea and headache, causing restlessness and preventing sleep for a portion of the night.

These symptoms occurred for the last time on May 12th, and by May 15th I felt quite fit save for a certain amount of lassitude. This gradually subsided.

No signs of rickettsia bodies were visible in the smears made from the excreta of the lice in my boxes until the eighth day after I recommenced feeding them; then a smear of the excreta from the only box that I was able to keep warm, in the pocket of my pyjamas, until the incubator at the laboratory was available, showed a few rickettsia bodies in several of the fields examined. This box (a) was two days ahead of the remaining five boxes in the matter of incubation, though the chances of infection in all the boxes dated from the same time.

The details of incubation after the first infecting meal are as follows: Box (a), two days at an estimated temperature of 85° to 90° F. The other five boxes, except during feeding times, remained during this period at about 60° to 65° F. After this, all the boxes were kept in an incubator except when the lice were being fed. The temperature of the incubator varied occasionally between the limits of 90° and 100° F., but usually it remained at 93° F. Smears of excreta from box (a) showed a quite convincing rickettsia infection on the ninth day, while on the tenth and eleventh days these bodies were present in great abundance in the excreta from box (a), and were present in small numbers in most of the smears made from the excreta out of the other boxes. From the twelfth day onwards all the boxes were heavily infected. Smears of guts dissected out of adult lice taken from the boxes showed about 60 per cent. of easily recognizable infections. Out of some fifty sectioned lice taken from the boxes the percentage showing a general infection of the gut was somewhat lower than in the case of the smears, but a prolonged examination of the apparent negative instances often revealed a slight local infection where folds in the gut wall are of most frequent occurrence.

In no case was any evidence of intracellular infection discovered although careful search was made for it. The gut walls, which seem to be so favourable a situation for the development of *Rickettsia quintana*, were, however, generally more or less lined with them, in some cases so uniformly as to give the appearance of palisading.

My blood remained infective for lice after all the symptoms had completely disappeared. Ora from my stocks were washed on May 17th for several minutes in 4 per cent. lysol and then in running tap water for thirty minutes, they were then dried, put into a clean box, and the lice after hatching were fed upon myself; excreta from this box showed the presence of rickettsia bodies on June 11th and 21st.

Ora from my boxes were washed in the same manner on June 11th and placed in two clean boxes to hatch, the lice in one of the boxes being fed by Dr. Arkwright and those in the other by myself. Smears made of the excreta from these boxes showed that the insects fed by Dr. Arkwright were free from rickettsia bodies on June 28th and July 5th, whereas those fed by myself gave positive results when

tested on June 28th, July 29th, and August 2nd and 6th. Lice were taken from Dr. Arkwright's box on July 20th, placed in a new box and fed upon myself; excreta from this box remained free from rickettsia bodies for ten days but showed them on the fourteenth and eighteenth days.

Ova of *Pediculus capitis* taken from one of my boxes on August 6th and washed in the manner already described were placed in a new box; the lice which hatched were fed on myself, and the excreta from this box showed a slight infection with rickettsia bodies on September 8th, but subsequent tests of excreta from this box, and also from the one containing lice from Dr. Arkwright's stock, have shown no trace of rickettsia bodies up to mid-October. That is to say, lice fed upon my blood four months after an attack of the disease and three months after the disappearance of all symptoms developed the organisms in their guts, so that it would not seem improbable that the occurrence of rickettsia bodies in the lice from healthy persons was due to the lice having fed on a convalescent from trench fever.

CONCLUSIONS.

1. Trench fever patients may remain capable of infecting lice with *Rickettsia quintana* for at least three months after the cessation of febrile attacks or other obvious symptoms.

2. Persons in apparently good health may therefore infect lice with *Rickettsia quintana*.

3. Lice infected with rickettsia bodies indistinguishable from *R. quintana* were present in Warsaw in 1920, and were associated there with a case of trench fever.

3. Volbach, S. B., Todd, J. L., and Palfrey, F. W. (1920): A Preliminary Report from the Typhus Research Commission of the League of Red Cross Societies to Poland, *Internat. Journal of Public Health*, vol. 1, No. 2, September, 1920.

RECENTLY the French Minister of War asked the Académie de Médecine several questions with regard to the best age and most suitable time of the year for calling young men to the colours. He asked whether it would be better to call them up at the age of 19, 20, or 21. The Académie, in its reply, while pointing out that growth in man does not cease until 25, stated that the age for incorporation in the army might be 20, but that the medical examination at that date should be very strict. The end of April was considered the best time for calling up the class of that year, but if a second call was necessary it was thought that it should be made during September. The best barracks available should be used for housing young soldiers, who should be supplied with a complete change of clothes, to be used when they come in tired and wet. The food, it was stated, should be abundant, varied, and prepared by trained cooks.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

DEXTROSE IN CARDIAC FAILURE.

EARLY in 1912 my attention was drawn to the fact that a 5 per cent. saline solution of glucose was of great benefit in post-operative shock; I was able fully to corroborate this in several cases of my own; when the patients showed marked signs of collapse following an abdominal operation, one pint of a glucose saline solution injected per rectum had the effect of tiding the patient over this critical period, and every one made a complete recovery.

On October 15th, 1920, I was called to see a gentleman, aged 70, who two years previously had contracted pneumonia, and a small unresolved patch at the base of the right lung had remained; I found that the patch had again become active; the pulse was 108, respirations 36, and the temperature 99.6° F.; he had a persistent irritating cough with mucous râles all over the right side, with all the signs of an active bronchopneumonia. For several days the pulse kept between 102 and 108, and intermittent; the respirations were shallow, with numerous moist râles all over the right lung, more particularly at the base; the left lung was comparatively free. He was sleepless owing to the cough.

On October 19th the base of the left lung became involved. The temperature was between 98.4° and 100° F., respirations 48, pulse 104, with marked intermittency. Cough was very troublesome and the patient was sleepless. He remained in this condition for the next few days, but showed signs of getting weaker, and on October 24th he required an injection of hypophysis 1 c.cm., as the pulse showed signs of failure. The temperature was now between 97.6° and 98° F., and respiration was hurried and shallow; the lungs showed no signs of improvement, while the heart laboured with marked arrhythmia. As his nights were the worst, and he was unable to lie down, he received an injection of hypophysis once or twice throughout the night.

About 3.30 a.m. on October 26th I was hurriedly sent for owing to his sudden collapse. The extremities were cold, the pulse almost imperceptible, heart sounds faint and very irregular; the temperature 95° F. With appropriate remedies he revived; oxygen was given. The temperature gradually rose until it reached 97.6° F., the pulse 92, small and intermittent; respirations 42.

On October 30th a 5 per cent. solution of dextrose was administered in teaspoonful doses every fifteen minutes. Throughout the night he suffered from wandering delirium, his speech was indistinct. The respirations would fade away, then become somewhat stertorous, only to die away again. After the continuous exhibition of the dextrose solution for thirty-six hours the respirations had become natural although still rapid, the temperature still subnormal, but the mental apathy completely gone. The heart was regular.

I now gave him hypophosphites with hydriodic acid and 5 drops of the digitalis; the chest began to clear. By November 12th the chest had almost entirely cleared up; the pulse was 72 and regular, and the heart sounds normal.

I have recorded this case in the hope that others will give dextrose a more extended trial in cases of cardiac failure. My experience previously had only been in operative work, and its success was so marked that the idea occurred to me that to give small doses continuously for a lengthened period would achieve the same effect as giving a rectal injection.

G. SCOTT MACGREGOR, M.D.,
Senior Surgeon Glasgow Hospital for Women.

TUBERCULOUS HAEMARTHROSIS OF THE KNEE.

So far as the writer is aware the condition here reported is a very rare one, only a few cases being on record.

The patient, a girl of 15, was admitted to Duke Street Hospital suffering from multiple tuberculous lesions. The glands of the neck were involved; she had tuberculous dactylitis, and there were small lesions in connexion with the epiphyses of the left wrist, right ankle, and right elbow. Wassermann reaction negative. No history nor evidence of haemophilia.

The patient was placed in bed with extension, on account of the condition of the right ankle-joint, which was swollen and tender; but she was allowed up when the condition of the ankle improved.

The right knee had been painful upon occasion from the time of admission, but the pain now became gradually worse and more constant, and, upon slight swelling of the knee-joint occurring, extension in bed was reapplied. The

extension relieved the pain, but it did not disappear entirely and the swelling became more marked, until about three weeks after return to bed the swelling rapidly became extreme, while the pain was severe.

An exploratory puncture was therefore made, and a large quantity of dark fluid blood, together with a few clots, was evacuated, after which the joint resumed its normal size. A firm bandage was applied and the patient felt greatly relieved. The improvement continued for about ten days, when the joint again became rapidly distended, and a further quantity of blood was evacuated. Horse serum was given to promote the coagulability of the blood, but a third bleeding occurred a week later and the blood was evacuated.

Thereafter there was no further haemorrhage and the patient's health steadily improved, but the joint remained slightly swollen and tender, and the synovial membrane distinctly pulpy.

JOHN A. C. MACEWEN,
Surgeon, Glasgow District Hospitals; Honorary Surgeon,
Erskine Hospital for the Limbless.

ABDOMINAL TUMOUR FOLLOWING INJURY TO THORAX.

PRE. X, a young man, was admitted to hospital in France labelled "N. Y. D. abdomen." He complained of intermittent pain and discomfort in the upper left abdomen, with occasional vomiting and weakness; these symptoms extended over some months. He gave no history then of any injury; none was suspected, nor was there any apparent evidence of such.

The patient did not look ill. Palpation of the abdomen showed marked resistance over the left hypochondriac region. He was given fluids and watched. The symptoms continued with slight occasional rises of temperature and slightly quickened pulse rate. No diagnosis was made, but possibilities were thought of—none in the right direction, however. A week after admission he was taken to the operating theatre. Abdominal palpation during induction of anaesthesia showed resistance markedly present until he was fully under, when a definite tumour, moving with respiration, could be made out in the uppermost part of the left upper quadrant. On laparotomy I found a large puckered ball of great omentum lightly adherent to the left half of the diaphragm, which was reddened. The omentum was easily unrolled and placed in its normal apron position. The wound being closed and sealed off with aeroplane varnish, a second vertical incision was made in a line external to the nipple, over the seventh and eighth costal cartilages. Pus was found and these cartilages were eroded. The cavity was scraped, flushed, and drained. Both wounds healed quickly and no abdominal symptoms recurred.

On being interrogated the patient subsequently stated that he had been kicked in the left lower chest some months previously. The case, therefore, seems to demonstrate excellently that the "abdominal policeman" was as usual unremitting in attention to duty—in addition to his own regular "beat," he was in readiness to deal promptly with an intruder from an outside source.

F. J. STRACHAN, M.C., M.D., B.S.
Dunreggan, Troon, Ayrshire.

GLANDULAR AND PULMONARY TUBERCULOSIS.
A VERY constant, if not invariable, fact I have observed in my fifty years' experience of tuberculosis is that those members of families with an inherited predisposition to the disease who suffer from cervical gland lesion leading to suppuration do not get pulmonary tuberculosis, or, indeed, any other form of the malady; whereas several other members of the same families without gland lesion, and often the more robust individuals, frequently develop consumption. All my cases have also shown signs that the apex of the corresponding lung had been affected but had recovered. Depression and dullness were present in some cases, but in all there was condensation, as shown by very marked increase of vocal resonance.

Can, then, the absorption of tubercle bacilli from the surface of the mouth when conveyed by the lymphatic vessels and arrested in the glands, as indicated by these glands breaking down, lead to the production there of a type of bacillus capable of curing consumption and of conferring immunity without the bacilli themselves going beyond the glands? That is, I think, what is to be inferred from the above account.

Consulting Physician, Royal Southern Hospital, Liverpool.

Reports of Societies.

TREATMENT OF INOPERABLE UTERINE CARCINOMA.

At a meeting of the Section of Obstetrics and Gynaecology of the Royal Society of Medicine, held on January 6th, with the President, Professor HENRY BRIGGS, in the chair, Mr. PERCY P. COLE read a paper on a series of forty-three cases of inoperable uterine carcinoma treated by the cold cautery method of Percy. He felt impelled to make known his experience of this method, as it had been the subject of considerable criticism in America. Owing to this adverse criticism the method had not been supported in this country, and, although other cautery methods had been employed, the speaker was under the impression that his experience of this particular method was unique. He laid much stress on the value of unvarying assistance, and expressed his obligation to Mr. O. T. Dinick, who had assisted him at most of the operations.

The technique of the operation could be divided into (1) abdominal—the abdominal cavity being freely opened by subumbilical incision, and the internal iliac arteries, the ovarian vessels, and the r of the vagina being dilator, until the made. This speculum had a surrounding water jacket space, through which water circulated and so protected the vaginal wall from damage by the heated cautery. Redundant growth was removed by a sharp curette and the cautery then directed through the cervix into the uterine cavity. From this time onwards the direction of movements of the cautery were controlled by the assistant, either by verbal directions or by movements, his hand inside the abdomen grasping the fundus of the uterus. Two degrees of heat had been employed—a high or destructive degree and a low or cooking degree; the degree of heat had to be estimated by the abdominal assistant, and might be considered by him sufficient when the heat transmitted through the tissues to his palpating hand was such as to be just bearable. When fundus and cervix had been treated, outlying areas in the bases of the broad ligaments were dealt with, particular stress being laid upon the care necessary to avoid overheating when dealing with the anterior vaginal wall. Failure in this respect had led to the formation of a vesico-vaginal fistula. It was freely admitted that this post-operative complication was most distressing to the patient, and was, in fact, the chief drawback of the procedure. When the pelvic contents had been efficiently treated the pre-operation rigidity had given place to a softness and mobility which were both unexpected and characteristic. Viewed from below the cervix presented a large funnel shaped crater, the sides of which were quite firm, perfectly dry, and of a peculiar greyish-yellow colour. When the cauterization had been completed the abdominal wall was sewn up in three layers by the assistant. In 1914 ligation of vessels was not undertaken by Dr. Percy, but the ligation of the iliacs, and other vessels to the uterus, was carried out by Mr. Cole on account of severe secondary haemorrhage, which the first few cases clearly showed to be dangerous to the uterine arteries. In internal iliacs, a greater risk being vein as it lay behind the artery.

Gauged by any standard of selection, the type of case dealt with in this series of forty-three was inoperable; the cases were recruited from inoperable cases so certified by practitioners, or admitted to the Cancer Hospital from the out-patient department, their condition being verified in every case by the visiting staff. The almost constant presence of pyometra, as revealed at operation, was commented on, and the extraordinary immediate improvement in the appearance of the patients could best be accounted for on the assumption that pyometra was the causative factor. The comparative rarity of demonstrable glandular invasion had been remarkable, and it was suggested that this freedom was not only apparent but real, for Leitch, in a series of 915 post-mortem examinations, had found that metastasis of any kind occurred in only 405, or 45 per cent. In other words, 55 per cent. of cases which had run their course without surgical intervention had died as the result of effects determined by what had remained to the last a local lesion. Dilatation of the ureters—sometimes to an extreme degree—had been frequently noted: and, again, it was pointed out that Leitch in his series of 915 cases had found the kidneys hydronephrotic and the ureters dilated in 75 per cent.

As regards the progress of these cases, the abdominal wall had healed without suppuration in every case. Temperature and shock had been absent, and an immediate improvement in the patient's appearance had been

consistently noted, yet several of the patients were over 50, and one was aged 68. A foul discharge might commence on the third or fourth day and exist for a fortnight or so; this was best treated by the administration of a weak iodine douche. Patients had been kept in bed for three weeks, and had left the hospital at the end of a month. Vesico-vaginal fistula had resulted in seven cases; in those cases leakage might have diminished somewhat, but healing had never taken place. This most uncomfortable complication was, however, a frequent result of the untreated disease, and it was urged that vesico-vaginal fistula with freedom from malignant disease was, at any rate, preferable to a vesico-vaginal or recto-vaginal fistula with all the accompaniments of progressive and septic cancerous infiltration. Mr. Cole had no desire to conceal the fact that failures had been frequent, but as the cases dealt with by him could not conceivably be made worse, any improvement was to the good. He exhibited three cases:

(1) A young woman, now aged 35, upon whom operation had been performed nearly three years ago, and examination by members of the Section had failed to reveal the existence now of any demonstrable malignant disease. (2) A woman aged 45, operated on one year ago, was free from discharge and pain since the operation and was now enjoying good health. (3) A woman, now aged 71, operated on three years and three months ago, had a vesico-vaginal fistula, and, although she found the fistula a source of great discomfort, she was yet quite emphatic that life was worth living; she also was recorded as now being free from demonstrable malignant disease.

It had been found latterly that the following up of these cases by the implantation of radium needles had given good results, and Mr. Cole was of opinion that this conjoint treatment by cautery and radium held out to these patients the best chance of palliation and temporary relief from distressing discharges, together with a chance of a very materially increased term of useful life.

Morphine in Labour.

Dr. LOUISE McILROY read a short communication on the use of morphine in labour, based upon the results of the administration of morphine in obstetrical cases occurring in the officers' wives' section of the 82nd General Hospital, Constantinople. A large number of civilian patients were also admitted for treatment, including Turkish, Greek, and Russian women. The majority of the patients were primiparae, and the cases were not selected, but morphine was given in complicated cases, such as malpresentations, albuminuria. No vaginal examinations were made, except in cases where complications were suspected. No douching of the vagina was carried out. Morphine was given in the form of tablets of morphine sulphate hypodermically in the upper arm. The initial dose was $\frac{1}{2}$ grain, and repeated doses of from $\frac{1}{2}$ to $\frac{3}{4}$ grain were given at varying intervals throughout labour, according to the condition of each patient and her capacity for bearing pain. There was no excitement observed nor mental confusion; the patients slept at intervals and awakened refreshed. The uterine contractions only showed apparent or temporary diminution, and the progress of the labour was found to be hurried rather than delayed. After some experience of the effect of the drug, it was given, not with the primary object of allaying pain, but of shortening labour. Thirst was increased, restlessness was diminished, the third stage was unaffected, and no risks were apparent with regard to the child. No post-partum haemorrhage was observed; less fatigue and absence of shock caused a favourable convalescence after labour. The constant attendance of the medical practitioner was not required, as in the administration of scopolamine-morphine. The results were satisfactory and gave this drug a useful place in the management of labour.

Dr. HERBERT WILLIAMSON did not agree with Dr. McIlroy as to the absence of effect on the child; in his experience, if the drug were given within two or three hours before the birth of the child, the latter was born in the condition known as oligopnoea. If left alone, the child generally came round all right.

Dr. HERBERT SPENCER said that in his opinion and in the opinion of many obstetricians before his time, opium, in solid or liquid form, was a much better sedative in labour than morphine. He felt sure that morphine endangered the child's life when given repeatedly up to shortly before its birth. It could not be too strongly

insisted upon that the repeated administration of powerful drugs as a routine measure was neither necessary nor advisable in ordinary healthy women.

Dr. AMAND ROUTH asked how was the shortening of the first stage caused. Was it by the lessening of the rigidity of the cervical muscle as after chloral? Apparently in the second stage there was some muscular relaxation of the pelvic voluntary muscles, and some lessening of the abdominal reflex contractions, but further observations were essential.

Dr. LAPHORN SMITH said that in all cases of primiparae it was his practice to prescribe a mixture with 30 grains of sodium bromide and $\frac{1}{4}$ grain of morphine to the dose, to be given as soon as labour began and repeated four-hourly. Nurses had called his attention to the excellent condition of patients after labour in these cases. He repeated the morphine by hypodermic injection when required.

PELVIMETRY IN CONTRACTED PELVIS.

At a meeting of the Edinburgh Obstetrical Society held on January 12th, with Dr. HAIG FERGUSON in the chair, a paper was read by Dr. DAVID SHANNON, Glasgow, on pelvimetry as an index of treatment in contracted pelvis. His observations were limited mainly to pelves deformed at the superior strait, and the motive of his paper was to endeavour to prove that, except in a few cases, the measurement of any diameter at the pelvis could not be used alone to indicate treatment and to bring forward a method of pelvimetry which could be used as an index of treatment in all cases. The normal minimum of the pelvis had been laid down by Michaelis and Litzmann, but judging from textbooks, in which such a marked variance existed regarding pelvic measurements, their standard had not been accepted, with the result that it was difficult for a practitioner to say when a pelvis was really contracted, and certainly he could not base treatment upon such measurements with confidence. It was very difficult to measure a pelvis accurately, and the deductions in many cases from such measurements could not be trusted sufficiently to guide one as to the best treatment to adopt.

Dr. Shannon illustrated his contentions by referring to a series of 316 cases of contracted pelvis, in which he outlined the treatment carried out. The pelves were grouped in such a way that the conjugates of the superior strait measured the same in each group. For example, in that group in which the conjugata vera measured $3\frac{1}{2}$ in., 34 per cent. were born spontaneously, but amongst the other cases almost every obstetrical operation was performed. Pelvic measurement, he stated, could be used as an index of treatment, provided the foetal head did not vary in size and consistence, but as it did so often vary it was essential to estimate its size relative to the brim of the maternal pelvis in each case before treatment could be decided upon. On that account, therefore, the foetal head was the best pelvimeter. This fact was appreciated by many obstetricians, notably Müller, Pinard, and Munro Kerr, each of whom had given us a method of determining this important factor. Munro Kerr's method was a distinct improvement on the others, and, with a little practice, could be used as an excellent index of treatment in these difficult cases. This method of estimating the relative size of foetal head and pelvic brim Dr. Shannon proceeded to describe in some detail.

In pressing the foetal head on to the superior strait of the pelvis it was advised to imitate Nature. In pelves of the flat variety downward pressure should be made, so that the sagittal suture lay in the transverse diameter of the pelvic brim. In most cases this was easy, but in some—those in which the occiput was posterior—it was noticed that the head often lay in the oblique diameter, and, in such cases, it had to be changed into the transverse before pressure downwards was made, if the best results were to be obtained. In generally contracted pelves, also, the head did not always lie well placed and in an oblique diameter, and so, in pressing it downwards, care had to be exercised so that the head entered the oblique Nature intended it to enter. These abnormal positions of the head were first noted by palpation and verified later whilst performing Caesarean section by the lower uterine segment incision. If the foetal head was pushed down on to the superior strait carelessly there was a possibility that a certain amount of lateral flexion of the head might take place, with the result that the amount of overlapping of the head over the symphysis pubis would be more apparent than real. It was to be noted that the thumb, by which the amount of overlapping at the symphysis pubis was estimated, was the principal part of Kerr's method,

and differentiated it entirely from the methods of Müller and Pinard. The thumb should be laid flat on the outside of the symphysis and flush with its upper border. A full bladder and a pendulous abdomen, especially in primiparae, made the estimation of overlapping difficult. A loaded rectum, tumours, or a placenta lying behind the foetal head pushed the head forwards so that the overlapping was exaggerated. Occipito-posterior cases in generally contracted pelves overlapped more than those in which the occiput was anterior. The maximum amount of overlapping was not palpated at the centre of the symphysis but to one or other side. In flat pelves the greatest amount of overlapping was noted just immediately above the upper margin of the symphysis pubis, but in generally contracted pelves the thumb had to travel above this point to arrive at the seat of greatest disproportion. This was specially true in occipito-posterior cases.

It was as an index of treatment that Kerr's method was of such value, and Dr. Shannon detailed the procedure as carried out by him in his own wards, dividing contracted pelves, with a view to treatment, into four groups, according to the amount of overlapping of the foetal head at the symphysis pubis.

Group A.—The foetal head, on pressure, sinks into the pelvis. There is no overlapping, although the pelvis is contracted. With a patient in labour such a case is treated as normal and a spontaneous termination expected. If not in labour, she is requested to return for examination at a later date.

Group B.—This comprises cases in which overlapping is of minor degree. The head does not enter the brim. It "bites." Measured by the thumb, the overlapping is not flush with the outside edge of the symphysis pubis. If those cases are in labour, they should be left to Nature. The forces of labour will obliterate the disproportion and a spontaneous birth can be expected. If not in labour, this is the best time to induce it prematurely, provided the child has reached the thirty-sixth week of intrauterine life.

Group C.—In this group there is a medium amount of overlapping. The thumb informs one that the head is flush with, and in some cases overlaps to a slight degree, the outside edge of the symphysis pubis. In those cases one hopes for a spontaneous birth. With that object in view patients are allowed to go on in the second stage for four, six, eight, or twelve hours. During this time the condition of mother and child must be carefully observed. Forceps are applied when the indications for the operation arise, and, should they fail to deliver, pubiotomy is resorted to.

Group D.—The foetal head bulges over the symphysis pubis so much that the overlapping can be seen in many cases, and often the disproportion is so great that the top of the thumb, as it lies in position, is partly covered by the part of the head that overlaps. In such circumstances one infers that no amount of moulding can diminish the diameter sufficiently to allow the head to come through the contracted brim, so one has no choice but to perform Caesarean section, if the child is alive, and craniotomy, if the child be dead.

Dr. Shannon referred to the difficulty of treatment in these cases, and laid stress on the fact that, before treatment could be efficiently indicated by Kerr's method, the following factors had to be carefully determined and their relationship one to the other accurately considered as far as was possible:

1. Pelvic measurements, to determine type of pelvis.
2. Consistence of foetal head.
3. The variety of biparietal obliquity.
4. The position of foetal head in pelvis.
5. The expulsive forces of labour.

Dr. J. W. BALLANTYNE thought Dr. Shannon's paper might be termed the scientific specialization of Barbour's dictum that the foetal head was the best pelvimeter. Dr. Shannon had said nothing about the cephalometer, and he concluded that Dr. Shannon's experience agreed with his own, that the results were fallacious.

Dr. LACKIE agreed that the usual estimation of the size of the pelvis from measurement was unsatisfactory in affording a guide to treatment in many cases, especially in the medium variety of contractions.

Dr. HAIG FERGUSON pointed out that the early descent of the head into the pelvis, which commonly occurred in a primipara before labour, explained why a second labour, in which the head had developed till full time above the brim, might be attended with greater difficulty.

Double Congenital Hydronephrosis.

Drs. R. W. JOHNSTONE and F. J. BROWNE afterwards read a paper on a case of double congenital hydronephrosis. The child, a female infant weighing 6½ lb., appeared normal, but died without any apparent cause six hours after birth.

At the post-mortem examination the histological appearances of lung and liver suggested syphilis, but the father's Wassermann reaction was negative, and sections of the foetal organs

stained by Levaditi failed to show spirochaetes. The right side of the abdomen was occupied by a cyst the size of a cricket ball and connected with the right kidney. The left kidney seemed normal, but only about half the usual size. Microscopically the kidney showed a marked increase of the interstitial connective tissue with few tubules, those that were left being dilated, in some cases to form small cysts. The right ureter was thickened by new fibrous tissue, the muscle being diminished in amount. The left ureter was completely obliterated during part of its course by fibrous tissue.

The condition seemed to be primary in the ureters, and due to a chronic inflammatory change involving chiefly the muscular coat, and causing stenosis and obliteration of the lumen with secondary changes in the kidneys.

At a general meeting of the Camberwell Division of the British Medical Association, held on January 5th, at the Camberwell Infirmary, with Dr. A. F. HEALD in the chair, in the course of an address on "One or two points of medical utility," Dr. HERBERT FRENCH stated that in cases of so-called primary acute nephritis some focus of infection could generally be found somewhere in the body, and expressed the opinion that in many cases the tonsils were at fault; he quoted interesting cases in support of his theory. Dr. LLOYD referred to the occurrence of albuminuria in many cases of impetigo in children, and other speakers drew attention to pyorrhoea, and especially scarlet fever, as similar causes of nephritis. Dr. FRENCH also spoke of the good effect simple puncture had in many cases of delayed resolution in pneumonia, even in cases in which no fluid was obtained, but could offer no explanation of this phenomenon. Lastly, he referred to the good effect that could often be obtained by the administration of small doses of thyroid extract in the periodic sick headaches of women.

A PATHOLOGICAL MEETING of the West London Medico-Chirurgical Society was held on January 7th at the West London Hospital, with Dr. F. J. MCCANN, the President, in the chair. A series of interesting pathological specimens was shown by Mr. W. MCADAM ECCLES, Dr. W. H. WILLCOX, and other members.

Reviews.

THE PREVENTION OF VENEREAL DISEASE.

The book, *Prevention of Venereal Disease*,¹ by Sir ARCHDALL REID, is addressed, on the one hand, to those who would prevent venereal disease in themselves, and on the other, to those who would prevent it in the community; it is endorsed by the Society for the Prevention of Venereal Disease, and contains the evidence and arguments on which that Society bases its policy. It has a preface by the author, and an introductory chapter by Sir Bryan Donkin.

That part of the book which deals with the means for preventing venereal disease by means of prompt disinfection is built on the foundation of some extraordinarily good results obtained by the author during the war amongst soldiers in the Portsmouth area and by Surgeon Commander Boyden amongst sailors at Whale Island. The figures as given are as follows:

Sir A. Reid: Average number of troops 2,000. Rate per 1,000 per annum, 1.5. Six cases of gonorrhoea and one of syphilis. Of these men, two infected by their wives, two (drunk) took no precautions, one only just arrived in camp not instructed and took no precautions, and two did not use disinfectant till more than one hour after risk run.

Surgeon Commander Boyden: 496 men used disinfectants. One case of syphilis: he used it six hours after exposure.

These figures will be accepted by anyone who has any knowledge of the subject. There is only one weak spot in them, and that is that he was dealing with a very shifting and migratory population. It is not possible for him to say how many men may have become infected before leaving his medical charge in whom the disease developed elsewhere, but for practical purposes this objection may be regarded as negligible.

That part of the book which deals with Sir Archdall Reid's method of early disinfection might well have been

compressed into a couple of pages, because, boiled down, it simply means that every person should have the knowledge that infection can be prevented by the immediate use of 1 in 1,000 solution of potassium permanganate, which, with a swab of cotton-wool for application, should always be carried on the person in a properly shaped and corked bottle for use as required.

But there is a good deal more than this in the book. The urgency of the problem is insisted upon, and here certain exaggerations, which are doubtless to be attributed to the enthusiasm of the writer, become at once apparent. He states, for example, that the prime cause of the German success in the spring of 1918 was the large number of British and Allied soldiers incapacitated in venereal disease hospitals! He states that almost every other person in the United Kingdom has, at some time or other, been infected with venereal disease, and that there are few, if any, families of which some members have not been infected. It is certain that numbers of practitioners with a great experience of practice, spread over many years, will demur to this. The problem is urgent enough, and there is no need to accentuate its gravity by even the slightest exaggeration.

A great part of the book consists of an interesting and well written dissertation on instinct and reason, inclination and morality, and a chapter on microbic diseases written so that it can be easily "understood of the people." The remainder of the work contains various statistics of disease in the overseas troops, with some pages on the findings of the Interdepartmental Committee and a verbatim report of the debate in the House of Lords on the motion for papers by Lord Willoughby de Broke. A great part of this section consists of controversial and polemical matter. Sir Archdall Reid has two King Charles's heads, the one "The Royal Commission on Venereal Disease," the other "The National Council for Combating Venereal Diseases." His condemnation of the Royal Commission, its composition and its report, and his imputation of unworthy motives on the part of its members which led to the issue of the report in the form in which it appeared, are exceedingly strong and intemperate. His particular objection is that the Commission took no evidence on Metchnikoff's discovery that the prompt use of calomel ointment after inoculation with syphilis in the case of apes prevented the development of the disease, and in its report ignored it. By not taking this evidence he states that the Commission betrayed its honour, did not play the game, and committed the offence which Englishmen hold unpardonable. The infection of soldiers, innocent women and children, and men, who were being poisoned by the many millions, was thrown into the scales, and against all this and against their own personal honour "the little members of this miserable little Commission put their most miserable little prejudices and found their prejudices the heavier." I have it from members of the Commission that no one ever suggested bringing the question of Metchnikoff's discovery before it. I am assured that had there been such a suggestion fullest inquiry would have been made and evidence courted. Sir A. Reid states that some of the medical members consulted whether they should introduce this subject, but abandoned the idea fearing prejudice and opposition. Therefore, the whole of the blame which he imputes to the Commission must rest on the heads of those medical members of it who, after consultation, decided not to bring a matter of such importance before it, and not on the unfortunate lay, clerical and female members, who, at that time, 1913-14, had probably never even heard the name of Metchnikoff or read of his discoveries. Such imputations on persons of the character of those who formed the Royal Commission are quite unjustifiable.

His second *bête noire* is the National Council for Combating Venereal Diseases. Because it does not see eye to eye with him it can do nothing right, yet he expends many pages in laying stress on the necessity for enlightenment of the public and the education of the very young in chastity and self-restraint, thus creating a "bias" in this direction, apparently quite oblivious, or ignorant, of the fact that this is the main plank in the platform of the Council, and has been preached both at public meetings and in private whenever possible on hundreds of occasions during the last five years. He states that ablation rooms were instituted by the Army Council despite the opposition of the National Council. As a matter of fact that body, through one of its Vice-Presidents, Sir Thomas Barlow,

¹ *Prevention of Venereal Disease.* By Sir G. Archdall Reid, K.B.E., M.B., Ch.B., F.R.S.E. London: W. Heinemann (Medical Books), Ltd. 1920. (Cr. 8vo., pp. 465. 15s. net.)

urged and helped in every possible way the establishment of these rooms throughout the army. Sir Archdall Reid considers that it possesses all the faults usual to scientific societies and teaching bodies which are under ecclesiastical control. As a matter of fact, on its medical and executive committees there are about thirty-eight medical members, one bishop, and one other minister of religion—the Rev. J. Scott-Liddell.

Sir Archdall Reid has not much belief in the efficacy of lectures in preventing the men running the risk of infection. He does not seem to have heard any lectures, and the one reported to him by his orderly (if the report be correct) was well calculated to make the judicious grieve. He states that, as far as he knows, no impression was made and the men looked on it as part of their ordinary work. The results of one lecture given to 3,000 young troops, as testified by the medical officer in charge, were even better than those obtained by Sir A. Reid by disinfection. Before that lecture the incidence of venereal disease was about the usual in that unit; after it, during three months in a country district, and five months later on in an East Coast town, swarming with temptations, there was only one case of venereal disease and that was caught three days before the lecture. Figures very nearly approaching this good result have been given to the reviewer by commanding and medical officers of the various dépôts where lectures were given at frequent intervals during the war. Their testimony is that the result of a lecture was that the men who were sick came for treatment, and afterwards, while that unit remained at the dépôt, the number of cases of venereal disease diminished from 50, 40, 30, as the case might be, to 3, 2, 1, or none.

But it is barren work to revive past controversies with regard to the forces. The army has melted into the civil population, and doubtless some of the 40,000 men who came under Sir A. Reid's instruction will remember and carry out his methods in civil life; doubtless a certain number of the 500,000 men (slightly less or more) to whom I have lectured will retain the impression which these lectures (*malgré* Sir Archdall Reid) made on them, but the problem at the present time is that of the civil population as a whole, not that portion which constituted the naval and military forces during the war.

The policy of the Society for the Prevention of Venereal Disease is, shortly, that all persons should be instructed in the fact that disinfection at the earliest possible moment after a risk has been incurred will almost certainly ensure immunity from infection. This means, since the first risk taken may be as fatal with regard to contracting disease as the fiftieth, that young persons should be instructed as early in life as may be possible. As most of the risks run are the result of an unpremeditated impulse or temptation they must learn that it is essential that the materials for such disinfection should be carried about continually on the person ready for use. Miss Ettie Rout, a member of the Grand Committee of the Society for the Prevention of Venereal Disease, crystallizes the policy of that society in the following words, quoted by the Archbishop of Canterbury in the debate in the House of Lords: "Every boy and girl in our parishes must be provided free with the outfit which will make them secure, and when you have done that all will be right—go with clean people and you will be clean."

The success obtained by Sir Archdall Reid was due to the fact that he is an extremely able, enthusiastic and energetic man. In the book he describes how he gave instructions personally to every man on joining his unit—if only one man paraded as a new-comer, that one man was individually addressed and instructed. In all cases where the method of rapid disinfection failed, the failure is attributed to the fact that the troops—Overseas or British—were not properly and thoroughly instructed. To deal with the civil population of more than 40 millions not under discipline in this manner is impossible. To ensure that each individual is thoroughly and personally instructed in the methods of disinfection by a medical practitioner as competent, skilled and energetic as Sir Archdall Reid is not practicable. To expect that young men, and young women also, will learn the technique of disinfection from leaflets, posters displayed in a public place, or printed instructions in a "packet," and proceed to carry it out satisfactorily is absurd. The result could only be to multiply enormously the number of risks which would be taken by persons who

would imagine that if disinfected they were absolutely safeguarded. To carry about a bottle and swab of cotton wool in the pocket would be a continuous suggestion an incentive to their use; and, as in many cases they would not be used properly, there would be a very much larger number of cases of failure than would occur if each individual were properly instructed by an expert. In addition, it must be remembered that the average individual would be apt to imagine that that which may prevent can certainly cure, and would use a disinfectant to treat the disease when developed—a result which would be disastrous to the individual and to the community.

Instruction is the keynote of the whole of the book, and it is pointed out that unless the instruction be efficient the results must be bad. Doubtless this book will have its uses—it will fortify with knowledge that man who, in a cold-blooded fashion, gratifies his passions; it will confirm him in the pursuit of his hobby, and in many cases will prevent the infection which might follow.

Should it be extensively read among the populace it will in my opinion, give the first push on the downward road of promiscuous sexual indulgence to numberless boys and girls. Boys, because they will take it that such a publication gives official, or semi-official, sanction to loose conduct, and therefore, under the shield of disinfection, will take the line of least resistance. Girls, because in their case, in addition to the promptings of passion, there will be added the allurements of probable "contraception" and possible disinfection. Of these thousands many, no doubt, will be protected, but in a large number of cases prevention will fail. Many a pitcher, rendered bold by immunity, will go too often to the well. A soldier in Co'ogue said to the reviewer: "I swabbed it off six times and thought I had the seventh, but I have just come out of 25 General." The probabilities are, therefore, that under such teaching the gross number of cases of disease will be increased though the percentage rate may be diminished. A warning that an indiscretion may be followed by disease will most certainly diminish the number of risks taken.

It is a pity that, in a controversial work of this sort, the author should be intemperate in his language and ready to impute unworthy motives to those who are just as anxious to diminish the incidence of this disease as he is.

E. B. TURNER.

PSYCHOLOGY OF THE SPECIAL SENSES.

In the introduction to the reprint of his Croonian Lectures on the Psychology of the Special Senses² Dr. Hurst says that his views on hysteria differ from those held by the majority of neurologists, but we cannot find that he gives an explicit account of what his views really are. We are disposed to infer, however, that they do not differ in any marked degree from those of Babinski, and that Dr. Hurst is in agreement with the majority of neurologists of experience. Like Babinski, he gives no answer to the fundamental question as to why among the many exposed to almost identical experiences in war and peace only a small minority should develop symptoms of hysteria. It is the answer to this question that we seek in vain equally among the writings of those who support the analytic method of investigation and those who, like Dr. Hurst, approach the problem of hysteria from an objective standpoint.

In conjunction with Mr. Gainsborough, the author studied the manifestations spontaneously presented by a number of healthy students, ignorant of medicine, who were instructed to pretend that they were suffering from paralysis due to an accident. The distribution of the mimic anaesthesia in these cases lends support to Babinski's dictum that between hysteria and fraud there is only a moral difference. So much is obvious, but it is not so clear why an absolute anaesthesia should never be found in the malingerer which will enable him to bear, without flinching, a severe painful stimulus, whilst such absolute anaesthesia is not uncommon in hysteria. Few clinical observers will, we fancy, endorse the experience of Dr. Hurst when he says he has never been able to find any evidence of cutaneous hyperaesthesia in "head's areas" in cases of gastric or duodenal ulcer when he has guarded against suggestion. Emphasis is laid on the absence of

² *The Psychology of the Special Senses*. By A. I. Hurst, M.A., M.D. Oxon., F.R.C.P. London: H. K. Frowde, and Hodder and Stoughton, 1920. (Demy 8vo, pp. 155; 29 figures. 12s. 6d. net.)

pharyngeal anesthesia as a stigma of hysteria, and it may be recalled that Iwanoff, in 1910, by observations on a large number of cases of hysteria, definitely disproved its existence.

A large section of the book is devoted to the subject of hysterical deafness. Here the author states that "the only test upon which complete reliance can be placed in the diagnosis of absolute hysterical deafness from absolute organic deafness is the presence of normal vestibular reactions in the former and their absence in the latter." But James, in 1882, found signs of vestibular reaction in 45 per cent. of deaf-mutes; Kreidl and, later, Golla found that about 50 per cent. of deaf-mutes gave a vestibular reaction; and Mygind found an intact labyrinth in 50 per cent. of his *post-mortem* examinations of deaf-mutes. The suppression in hysterical deafness of the "jump," or auditory-motor reflex, the site of which has been shown by Sherrington to lie in the mid-brain, is evidence of an active cortical inhibition that is suggestive of much in the pathology of hysteria rather than of "unswitching of the synapses at the level of the reflex or still lower."

It is clear that we are still a long way from any general agreement as to the nature of hysteria.

OPERATIVE GYNAECOLOGY.

ONE of the most interesting features of the second edition of Dr. CROSSEN'S *Operative Gynaecology* is his classification of the more important operations that have been devised for the treatment of prolapsus uteri. Not that he discusses or even mentions them *all*, but he classifies some hundred and ten of the more important modifications! This piece of work will be of value in enabling the less experienced operator, as the author hopes, to select the best operation in each individual case, and not to cleave to any one operation as if it could possibly be the best procedure in every case. The living pathology of prolapse differs so much in different cases that the prevalent tendency to do one operation, and one operation only, in the treatment of the condition cannot possibly lead to the best results.

The ordinary major and minor operations are well described, and many points, small but important, are brought out—points too apt to be overlooked in the pressure of routine work. The section on radical abdominal hysterectomy for cancer of the cervix is particularly full, and is illustrated in detail most helpfully, both as regards the various steps of the operation itself and the ureteral and other complications that may be encountered.

Dr. Crossen's book will be useful to gynaecologists and to surgeons embarking upon pelvic work. Its illustrations are very numerous and for the most part very helpful. There is, however, a lack of balance in the work, and it is extravagant to devote four pages to and to illustrate fully the operative treatment of such an exceedingly rare condition as syphilitic destruction of the urethra. Also it seems unwise and pathologically unsound, in the present state of our knowledge of it, to describe as a separate entity such a condition as acute pelvic oedema, of which only some five cases have been described. The author's textbook of gynaecology would be a more suitable place for the latter than an operative textbook. Apart from these slight weaknesses, however, it is a useful work, and both the author and the publishers are to be congratulated on a highly creditable volume.

PUBLIC HEALTH AND INSURANCE.

THE publication in book form of a number of *Addresses on Public Health and Insurance*, given by Sir ARTHUR NEWSHOLME in America, will be welcomed as giving the experience and opinions of one who was for eleven years the Chief Medical Officer of the Local Government Board. A considerable part of the addresses consists of a historical survey of the activities of the public health authorities of Great Britain, for which some remarkable successes are claimed. We are told, for example, that "between 1871-80 and 1910-12 in England the average expectation of life at birth for males increased from 41.4 to 51.5 years and for

females from 44.6 to 55.4, an increase within three or four decades of ten or eleven years in the average duration of life," which is equivalent to "an annual saving of 234,955 lives." Quite justifiably it is claimed that a large proportion of this improvement is due to the preventive measures carried out by public health authorities.

Sir Arthur Newsholme complains that the work of the health authorities has been hindered by the rigid boundaries within which their activities have been confined. "It was one of the misfortunes," he says, "associated with the deterrent policy of Poor Law administration in medical relief that separation between Poor Law and public health appeared to offer the best prospect of sanitary progress." The Report of the Poor Law Commission in 1909 fully recognized this fundamental mistake, and Sir Arthur repeatedly expresses his regret that action on the lines of the report was not taken. He thinks that "it would not have been an insuperable task to find a common measure of agreement between the majority and minority reports"; he contends that if the duties of Poor Law authorities had been transferred to the councils of counties and county boroughs, these authorities would have had a medical service of some 4,000 doctors with large infirmaries, and England would by this time have built up a national medical service freed from Poor Law shackles, and with a range easily capable of extension as needed. The national insurance system was adopted instead, and this he regards as a great calamity, which has delayed public health reform. In entering into this area of controversy it may be doubted if he does himself justice. He claims, but by no means proves, that the creation of the Insurance Committees, instead of handing over all medical functions to the public health authorities, was "one of the greatest blunders of the National Insurance Act." If the public health authorities and the Local Government Board itself had been far more perfect than they were, even in their limited domain, there might have been some ground for the claim, but it was not without the soundest reasons that on several occasions deputations from the British Medical Association strongly opposed the handing over of the medical functions to the Local Government Board. For many years the British Medical Association had agitated for a radical reform of the Local Government Board, but seemed powerless against bureaucratic influences; it was a blow to the bureaucracy of the Local Government Board when the National Insurance Act introduced for domiciliary treatment the totally separate *ad hoc* Insurance Committees.

It is somewhat surprising to find the author repeatedly saying that "the money in maternity benefit is given unconditionally" (pp. 95 and 111), for the Insurance Acts distinctly provide that maternity benefit "shall be administered in the interests of the mother and child in cash or otherwise"; the money gift is not unconditional. The model rules of approved societies make it clear that a mother must be attended at her confinement by either a doctor or a certified midwife, and a husband receiving maternity benefit is bound under penalty of imprisonment to make adequate provision to the best of his power for the maintenance and care of his wife during her confinement and for four weeks after her delivery. In addition to this, in numerous cases the societies have entered into agreements with suitable hospitals for in-patient treatment when required, thus administering part of the benefit "otherwise than in cash." Mistakes of this sort seriously detract from the value of the book. Nor does the author gain anything by belittling the work of the panel doctors, who have treated not only serious and chronic cases of disease best suited for home treatment, which no hospital would accept, but also enormous numbers of cases of incipient diseases where simple remedies and a few words of advice must often have prevented serious consequences. It is true, as the author says, that the national insurance scheme is restricted both as to the persons eligible and the range of treatment; Mr. Lloyd George claimed that the insurance scheme was a business proposition intended primarily for those who either could not or would not make provision against illness, and who could not or would not even pay their doctors' bills. As a business proposition the benefits and the range of medical services provided were strictly limited by the subscriptions, helped by a parliamentary subsidy from the State, and as a business proposition the insurance was able to weather the storm of the Great War when the local health authorities were almost stranded.

Operative Gynaecology. By HARRY STURGEON CROSSEN, M.D., F.A.C.S. Henry Kimpton, 1920. (Rox. 8vo, pp. 744; 5s. 6d.)

Insurance: American Addresses. By Sir ARTHUR NEWSHOLME, M.D., F.R.C.P. Baltimore: The Johns Hopkins Press, 1920. (8vo, pp. 234, 2.50 dols.)

of the infirmary, the patient paying his medical attendant independently.

3. That any extra nursing and any food or medicine ordered over and above those allowed under the ordinary tariff and pharmacopoeia of the infirmaries should be charged as extras to the patient.
4. That all medical attendance by private practitioners on "paying" patients in infirmaries should be under the supervision of the medical superintendent of the infirmary.
5. That infirmaries, so far as practicable, should be utilized for medical education.

These resolutions were submitted by Dr. E. W. G. Masterman to a meeting of the Infirmary Medical Superintendents' Society, who passed the following resolutions in connexion therewith:

- (1) That when in any infirmary there are beds to spare, after the needs of the poor in the district are met, it is desirable that accommodation should be provided for private patients, who would pay a fixed sum covering their expenses.
- (2) That if, and only if, separate wards can be provided for their accommodation, such patients should, if they desire, continue under the treatment of their own medical attendants while in the infirmary, subject to the general administrative supervision of the medical superintendent, and also, if they so desire, call in other consultants' advice at their own expense.

Meetings of Branches and Divisions.

METROPOLITAN COUNTIES BRANCH: HARROW DIVISION.

THE Division recently held three meetings to discuss the new record card for insured patients. These were held on January 4th, 14th, and 21st.

At the first meeting two resolutions were passed, after prolonged discussion. The first called attention to the objections to these records, outlined under five heads. The second had reference to the attitude of the Council in the matter, which was severely criticized, and to the correspondence of the Medical Secretary in the *Times*. The latter also was commented on very adversely.

On January 14th, as a result of these resolutions, the Division met again, to hear Dr. R. A. Bolam, Dr. Brackenbury, and Dr. Cox, who attended to put the case for the Association before the Division. The speeches of these visitors were of great assistance, and much information about the records and the press controversy regarding them was made available to the members. This meeting was adjourned to January 21st, as much remained for discussion, but before the adjournment a vote of confidence in the Medical Secretary was carried unanimously.

On January 21st another crowded meeting assembled, and many interesting speeches were made. A noticeable feature of several of these were the strong appeals for greater membership of the Association and for unanimity among the profession generally. As a result the following voting took place on these motions:

1. That the resolution embodying the Division's objections to the records be rescinded.
For, 8. Against, 7.

Many members refrained from voting, and it was agreed that the records should be discussed again in six months' time—after a trial of them had been made—the result to be reported to the Insurance Acts Committee.

2. That the resolution criticizing the action of the British Medical Association Council be rescinded.
For, 9. Against, 5.

Again a number of members did not vote.

The Division expressed its thanks to Drs. Bolam, Brackenbury, and Cox for having attended the meeting on January 14th.

METROPOLITAN COUNTIES BRANCH: WEST HERTFORDSHIRE DIVISION.

At a meeting of the Watford Ward of the West Hertfordshire Division, held on January 7th, the following resolution was unanimously adopted:

That this meeting of panel practitioners protests—

1. That the new medical record cards were not submitted, previous to their issue, either to the Divisions of the British Medical Association or to the Panel Committees for an opinion from those who had to use them as to their feasibility and usefulness.
2. That this meeting is of opinion (a) that it is a waste of practitioners' time to verify and supply particulars of a clerical nature, and that generally the time required for this work will be more than can be given by panel practitioners, except to the prejudice of their real work; (b) that in the winter and times of stress it will be impossible to keep accurately the record and therefore their value for statistical purposes is small; (c) that the record card should be kept by the insured; (d) that the record card being entered by the doctor when giving necessary particulars being entered by the doctor when giving necessary particulars should only be asked to attend; (e) that panel practitioners should only be asked to supply the information required under Clinical Notes and Diagnosis.

LANCASHIRE AND CHESHIRE BRANCH: ST. HELENS DIVISION.

Visit of the Medical Secretary.

A MEETING of this Division was held on January 21st in the Board Room of the Providence Hospital, a large attendance of members and others being present to hear Dr. Cox, who was ably supported by Dr. Garstang, Chairman of Representative Meetings. Both were accorded a hearty welcome.

Dr. Cox gave a practical address on the history and working of the Association, pointing out that the interest of every class of practitioner was catered for by the Association. He showed the advantages to all classes—consultants, general practitioners, those in the public health and other institutional services, and to the men serving in the navy and army. The audience was much interested and the address not unprofitable; the Divisional Secretary being later in a position to report the acquisition of four new members, and the reclamation of other two former members who had resigned.

An animated discussion followed, during which many questions were asked and criticisms offered, to which Dr. Cox replied.

Dr. GARSTANG also spoke and gave a lucid and interesting account of the administrative machinery of the British Medical Association and its committees. He impressed upon his hearers how greatly the Association was dependent upon the Branches, Divisions, and especially the members, for the proper and efficient working of that body, and how deeply their individual and collective responsibility was concerned. The meeting was unanimous in its expression of appreciation of the work of the Association, and the visit of the Medical Secretary has aroused in the Division a keener interest in the British Medical Association and its work.

SOUTHERN BRANCH: PORTSMOUTH DIVISION.

A WELL attended meeting was held on January 11th at Portsmouth, to which all medical practitioners resident in Portsmouth were invited, to discuss the attitude of the profession to the new panel record cards. After considerable discussion the following resolution was, on the motion of Dr. J. G. BLACKMAN, seconded by Dr. A. V. MAYBURY, jun., carried unanimously:

This meeting is of opinion that the present record cards are for the most part valueless, that they occupy valuable time which would be better devoted to the treatment of the sick, and moreover they violate the confidence which should exist between doctor and patient. That this resolution be sent to the Ministry of Health, local members of Parliament, and the press, and to the Friendly Societies Council.

The following motion, proposed by Dr. MCASKIE and seconded by Dr. NEWTON, was, after discussion, carried by a large majority:

That the record cards be kept (according to regulation), and only handed over under protest until secrecy is assured.

The question of whether the record cards would be available for use in legal cases was also raised.

On the motion of Dr. SHEAHAN, seconded by Dr. BLACKMAN, it was unanimously resolved:

That the Insurance Acts Committee in not offering the most strenuous opposition to the new system of record keeping has forfeited the confidence of practitioners working under the National Health Insurance Acts.

Association Notices.

MEETING OF COUNCIL.

THE next meeting of Council will be held on Wednesday, February 16th, in the Council Room, 429, Strand, London, W.C.2, at 10 a.m.

CHANGE OF AREAS.

Areas of Edinburgh and Leith, and Lothians, Divisions.

NOTICE is hereby given by the Council to all concerned that, as the result of a proposal to that effect by the Edinburgh and Leith Division, the Council has decided that as from January 29th, 1921, the following places (having been merged by the Edinburgh Boundaries Extension Act, 1920, in the City of Edinburgh)—namely, Colinton, Corstorphine, Cramond, Juniper Green, and Liberton—be transferred from the area of the Lothians Division to that of the Edinburgh and Leith Division.

BRANCH AND DIVISION MEETINGS TO BE HELD.

METROPOLITAN COUNTIES BRANCH: CAMBERWELL DIVISION.
—A meeting of the Camberwell Division will be held on Wednesday, March 2nd, when Dr. Hector Cameron, of Guy's Hospital, will give an address on Children.

METROPOLITAN COUNTIES BRANCH: EAST HERTFORDSHIRE DIVISION.—A meeting of this Division will be held at Hertford County Hospital on Wednesday, February 2nd, at 2.30 p.m. A lecture will be delivered by Dr. John Freeman (London) on asthma from the immunological point of view, at 3 p.m. Each member is asked to invite one non-member.

6 Miss F. Out of benefit 7 March, 1919 Removed Has since been attended by me—not charged fees Maintains she is in full benefit Absence of her new record card from my index would, in ordinary circumstances prove that she is not entitled

to benefit. Am I to charge her fees, and so risk depriving her of treatment of which she is really in need?

7. Mrs. G. Removed, "ceased", December 31st, 1919. Recently came up for treatment as an insured person. Referred to Insurance Committee. Has since been "reinstated," and four quarters' capitation fees have been credited to me. No explanation of this blunder (?). May I here point out, Sir, that had this insured person not come up for treatment when she did; or had my own bookkeeping been as faulty as that of the Government, I should have lost one year's capitation fee? The same observation applies to the other cases mentioned, but who knows to how many others who have not come up for treatment it is applicable?

The last case I would bring under your notice is of a different nature:

8. Mr. E. This man applied to be placed upon my list in March, 1920. He brought his own card and that of his wife. These were signed by me and sent, together with some half a dozen others, to the Insurance Committee on March 24th, 1920. Some two months later the man applied to me for his card—his wife's had reached her. Referred to the Insurance Committee, who, after several applications by the insured person, furnished him with his medical card, placing the man on my list as from July 30th, 1920, thereby depriving me of two quarters' capitation fees.

Many representations by me have failed to get this matter adjusted by the Insurance Committee. Now, Sir, upon what grounds do the Committee justify their action in this case? I sent up the card in March, and it is for the Committee to prove that it was received only in July. And I mean to say that I see no reason why I should suffer for the errors of the Committee.

In conclusion, Sir, I would say that if doctors are prosecuted for alleged frauds upon Insurance Committees and approved societies, I now confidently expect to hear that by your action in the cases I place before you the Public Prosecutor will get busy.—I am, Sir, your humble fellow-servant of the State,

London, W., Jan. 13th.

A. R. EATES, M.B.

Central Insurance Defence Fund.

SIR,—As one who has applied for the return of the balance due to me, might I suggest to my fellow conspirators who are doing the same that the amounts they receive should be handed over to the Royal Medical Benevolent Fund to augment the endowment? If half the men ask for a refunding of their money and put it to such a use the endowment of this fine institution would benefit to the extent of about £6,000, and the donors would not feel that their pockets were any the lighter.—I am, etc.,

Bridport, Jan. 20th.

C. EDWARDS, M.D.

"AN OLD KINGSLEYITE" writes: The Secretary has sent a letter to the subscribers to the above fund, saying that it is to be wound up. In brief the chief points are as follows: About £30,000 subscribed; expended, £18,000, for compensation, etc.; balance £12,000. The subscribers are entitled to receive the balance, which may be 12s. 6d. in the £. The Insurance Acts Committee with the Council of the British Medical Association, after careful consideration decided that the balance be transferred to a new trust called the National Insurance Defence Trust. The objects are set forth and are worthy of support. Already I have consulted some of the subscribers, and it is suggested that one-half should be devoted to the Defence Trust and the other divided equally between the Royal Medical Benevolent Fund and Epsom College. Both have special claims on the medical profession; both are in need of special financial help. The British Medical Association for many years, through the active assistance of our late general manager, Mr. Elliston, raised large sums. Some of the subscribers have died; others have removed, and their addresses are lost. Few, if any, would wish to have their subscriptions returned if they knew that these very worthy charities would receive their share.

DIARY OF SOCIETIES AND LECTURES.

LONDON DERMATOLOGICAL SOCIETY, 49, Leicester Square, W.C.—Thurs., 6 p.m., Chesterfield Lecture by Dr. W. Griffith: Parasitic Diseases of the Skin.

MIDDLESEX HOSPITAL MEDICAL SCHOOL.—Emeritus Lectures: Surgeon Rear Admiral Bassett-Smith, Tues., 3 p.m., Mediterranean Fever; Thurs., 3 p.m., Malaria.

ROYAL SOCIETY OF MEDICINE.—Occasional Lecture, Thurs., 5.30 p.m., Prof. F. Hobday: Diseases of Animals Contagious to Man. Section of Surgery: Subsection of Orthopaedics: Tues., 5 p.m., Cases; 6 p.m., Dr. G. Murray Leitch: Reactions and Electrical Treatment of Intrinsic Muscles of Foot. Section of Pathology: Pathological Laboratory, University College Hospital Medical School, Tues., 8.30 p.m., Dr. Penfield: Golgi Apparatus in Nerve Cells; Mr. Barrington: Fungus Parasite in Kidney of Rabbit; Dr. Walshe: Encephalitis; Dr. Lewis: Demonstration of Hyper-trophy of Haemoglobin. Thurs., 5 p.m., Cases; 5.30 p.m., Mr. G. L. Edington: Meckel's Diverticulum as a Cause of Intestinal Obstruction. Section of Obstetrics and Gynaecology: Thurs., 8 p.m., Mr. F. C. Pybus: Tuberculous Peritubal Cyst; Dr. T. W. Eden and Mr. F. L. Provis: X-ray Treatment of Fibroids and Chronic Metritis. Section of Laryngology: Fri., 4 p.m., Epididymus Demonstrations and Cases. Section of Anaesthetics: Fri., 3.30 p.m., Dr. Rowbotham and Dr. I. Magill: Anaesthesia in Plastic Surgery.

POST-GRADUATE COURSES AND LECTURES.

GLASGOW POST-GRADUATE MEDICAL ASSOCIATION, Victoria Infirmary.—Wed., 4.15 p.m., Mr. Parry: Surgical Cases.

HOSPITAL FOR SICK CHILDREN, Great Ormond Street, W.C.1.—Thurs., 4 p.m., Dr. W. J. Pearson: The Premature Child.

LONDON LOCK HOSPITALS.—Clinical instruction daily. Lectures: (Male Hospital; Dean Street) Mon., 5 p.m., Mr. Gibbs: Complications of Posterior Urethritis; Tues., 2.30 p.m., Mr. McDonagh: Nervous Syphilis; 5 p.m., Mr. Juler: Venereal Diseases of the Eye; Wed., 4.30 p.m., Mr. Joly: Acute Gonorrhoea in the Male; Fri., 4 p.m., Mr. Abraham: Gonorrhoeal Rheumatism.

MANCHESTER BABIES' HOSPITAL.—Sat., 3.30 p.m., Dr. Chisholm: Treatment of the Premature Child.

MANCHESTER ROYAL INFIRMARY.—Tues., 4.30 p.m., Mr. C. Roberts: Hernia.

MANCHESTER: ST. MARY'S HOSPITALS (Whitworth Street West Branch).—Fri., 4.30 p.m., Dr. Folbergill: Physical Signs in Abdomino-pelvic Surgery.

NATIONAL HOSPITAL FOR DISEASES OF THE HEART, Westminster, W.1.—Mon., 5.30 p.m., Dr. Goodall: Cardio-analysis.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen Square, W.C.1.—Daily (except Wed. and Sat.), 2 p.m., Out-patient clinics. Lectures—3.30 p.m., Mon., Dr. Greshfield: Cerebro-spinal Fluid; Tues., Dr. Collier: Headache; Thurs., Dr. Buzzard: Neuritic Affections. Demonstration of cases, Fri., 3.30 p.m.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.—Daily, 2 p.m., In- and Out-patient Clinics, Operations, etc. Lecture-demonstrations.—Mon., 4.30 p.m., Mr. Tanner: Surgical Cases; Tues., 3 p.m., Mr. Hayton: Vincent's Angina; Wed., 4.30 p.m., Dr. Alexander: Thyroid Insufficiency; Thurs., 3 p.m., Mr. Carson: Surgical Cases; Fri., 3 p.m., Mr. Gillespie: Cases of Surgical Interest.

SALFORD ROYAL HOSPITAL.—Thurs., 4.30 p.m., Mr. Jefferson: Gall Stones.

WEST LONDON POST-GRADUATE COLLEGE, Hammersmith, W.—Daily, 10 a.m., Ward Visits; 2 p.m., In- and Out-patient Clinics and Operations. Lectures—5 p.m., Mon., Dr. Saunders: Digestive Disturbances of Adults; Tues., Dr. Burnford: Morbid Anatomy of Digestive Tract; Wed., Mr. Armour: Abdominal Tumours; Thurs., Dr. Strangeways: Rheumatoid Arthritis; Fri., Mr. Baldwin: Appendicitis.

British Medical Association.

OFFICES AND LIBRARY, 429, STRAND, LONDON, W.C.1.

Reference and Lending Library.

THE READING ROOM, in which books of reference, periodicals, and standard works can be consulted, is open to members from 10 a.m. to 6.30 p.m., Saturdays 10 to 2.

LENDING LIBRARY: Members are entitled to borrow books, including current medical works; they will be forwarded, if desired, on application to the Librarian, accompanied by 1s. for each volume for postage and packing.

Departments.

SUBSCRIPTIONS AND ADVERTISEMENTS: Mr. J. H. G. (Financial Secretary and Business Manager).

MEDICAL SECRETARY (Telephone): Mr. J. H. G.

EDITOR, British Medical Journal (Telegrams: Aitiology, Westrand, London).

Telephone number for all Departments: Gerrard 2630 (3 lines).

SCOTTISH MEDICAL SECRETARY: 6, Rutland Square, Edinburgh. (Telegrams: Tel.: 4351 Central.)

IRISH MEDICAL SECRETARY: 47, Frederick Street, Dublin. (Telegrams: 4737 Dublin.)

JANUARY.

28 Fri. London: Central Ethical Committee, 2 p.m.

1 Tues. London: 10 a.m. 10 a.m. 10 a.m.

2 Wed. London: 10 a.m. 10 a.m. 10 a.m.

4 Fri. London: Medico-Sociological Committee, 2.30 p.m. London: Naval and Military Committee, 2.30 p.m.

16 Wed. London: Council, 10 a.m.

APPOINTMENTS.

DAVIDSON, Maurice, M.A., M.D. Oxon., M.R.C.P. Lond., Assistant Physician, Brompton Hospital for Consumption and Diseases of the Chest.

STRETTON, John Weston, F.R.C.S. Eng., B.Ch. Cantab., Honorary Surgeon, Kidderminster Infirmary and Children's Hospital.

BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths is 9s., which sum should be forwarded with the notice not later than the first post on Tuesday morning.

BIRTHS.

QUINLAN.—On January 20th, at Stanley House, South Roldish, Stockport, the wife of W. T. Quinlan, M.R.C.S., L.R.C.P., of a son.

WATSON.—On January 18th, at 33, High Street, Sheerness, the wife of F. H. Watson, M.B., B.Ch. Cantab., a son.

IN MEMORIAM.

DYER.—In ever loving, proud, and grateful memory of Francis N. V. Dyer, M.A., M.B., B.Ch. Cambridge, M.R.C.S., L.R.C.P. Lond., Captain R.A.F., late Surgeon R.N., who died of scarlet fever at the London Fever Hospital on January 24th, 1920, where he was Assistant Medical Officer, aged 25, the very dear and only child of Mr. and Mrs. Dyer, East Parade, Harrogate.

of shadows, though easy enough in many cases, is exceedingly difficult and sometimes misleading in others, for even the skilled worker makes oversights and errors in diagnosis. But the diagnosis of diseases of the alimentary tract by means of a meal opaque to x rays has opened a new field of research, which has already yielded results of great value, and calls for still more skill and experience in interpretation. Another promising field of usefulness is the therapeutic effect of x rays, properly administered, upon superficial skin lesions and upon deep structures like myomata of the uterus. In malignant disease, also, x rays have been shown to have a profoundly modifying effect, in most cases retarding and in a limited number definitely curative.

Electrology has become a sister subject, claiming also the whole time devotion of certain of its specialists. It includes the use of various forms of electrical currents—faradic, galvanic, sinusoidal, static—the use of high-frequency currents, and their most recent and powerful developments known as diathermy, especially the surgical uses of this last in canterizing, either superficially or deep in their substance, the affected tissues.

The Cambridge Diploma.

It is manifest that special training is needed by those who practise this art, and it follows that practice should be restricted to those who can show proof of such training. The first body to take the necessary step was the University of Cambridge, which established, in 1919, a Diploma in Medical Radiology and Electrology, to which we called attention a year ago.¹ The University Committee for the Diploma works in close association with the British Association for the Advancement of Radiology and Physiotherapy, which was the original moving spirit in the matter, and at present courses of instruction are given alternately in Cambridge, arranged by the University, and in London, arranged by the above named Association, the latter course being recognized by the University as qualifying for the examinations.

Courses of Instruction.

The first course was held in London during the early half of 1920, and there were 22 candidates at the June examination, instruction in physics being given at University College, whilst the teaching in radiology and electrology was given at the Royal Society of Medicine under the aegis of the Fellowship of Medicine, by the combined heads of the radiological and electrological departments of the leading London and other hospitals, with clinical work in the individual hospitals. The second course was held in the latter half of 1920 in Cambridge, the physics being done at the Cavendish Laboratory, and the University Lecturer in Medical Physics, Dr. J. H. Muller, receiving most valuable assistance from many of those who had held the first course. There were 15 candidates at the Christmas examination. A new course—somewhat modified as experience suggested—has just begun in London, the physics being, however, now done at King's College and at the Middlesex Hospital. A further course will begin at Cambridge next June.

The courses extend over six months; they include a special training in physics and electro techniques on the one hand, and in radiology (including the use of radium) and electrology on the other. The lectures in London extend over the whole six months; in Cambridge they are compressed into the Long Vacation and the Michaelmas Term, and arrangements are made for those taking the course there to gain additional experience between the courses of lectures by receiving clinical instruction in various London hospitals.

Further information as to the Diploma and as to the instruction in Cambridge can be obtained from Dr. Shillington Seales, Medical Schools, Cambridge; and as to the London course from Dr. Stanley Melville, at the office of the British Association for the Advancement of Radiology and Physiotherapy, 11, Chancery Street, Cavendish Square, London, W.1.

Lines of Advance.

There is another aspect which should not be lost sight of. The British Association for the Advancement of Radiology and Physiotherapy, as has already been said, was instrumental in getting the University of Cambridge to establish the diploma; it has organized the teaching in London, and its members have given generous assistance to the teaching in Cambridge. Further, it is arranging this year an International Congress in England. The primary object has been to advance the study of its subjects, and incidentally to raise the position of those practising them, so that the radiologist and

electrologist may obtain due recognition and status among their colleagues on hospital staffs. There are now few large hospitals in which this recognition has not been afforded. But above all, the association has shown the workers in these subjects the value of combined effort rather than of isolated individualistic work. If progress is maintained along such lines, or along modifications of such lines, we may see built up a British school of radiology and electrology which should attract workers from far and near, who, instead of attending the clinic of a single teacher, may obtain in their six months' course of tuition for the diploma both a special training and a knowledge of the special work of the leading English radiologists and electrologists. Funds are urgently needed to establish a small institute where research work can be undertaken.

THE OSLER MEMORIAL.

We announced some months ago that a representative committee had been formed for the purpose of raising a fund to provide a memorial to the late Sir William Osler. It was considered that the most appropriate form of memorial would be an Osler Institute of General Pathology and Preventive Medicine in Oxford. Osler began his life with his chief interests directed towards pathology, and he ended it with an enthusiastic belief in the future of preventive medicine. A large general committee was formed, and a smaller executive committee, of which the Bishop of Ripon—then Dean of Christ Church, Osler's college—was the chairman, and Dr. J. A. Gunn, professor of pharmacology in the university, the honorary secretary. The proposed form of memorial was approved at a public meeting held in Oxford on March 6th, 1920, and has met with general approval.

A preliminary list is given below of subscriptions which have already been received from members of the medical profession towards the fund which is being raised for a memorial to the late Sir William Osler. It is hoped that there may be others, whose attention has not been drawn to the memorial, who may wish to contribute. The fund now amounts to about £1,800.

Subscriptions may be sent to the Osler Memorial Fund, National Provincial and Union Bank of England, 91, High Street, Oxford.

LIST OF MEDICAL SUBSCRIBERS.

- £100.—Professor T. K. Monro.
 £25.—Dr. A. F. Hurst, Professor A. W. Mackintosh.
 £15 15s.—Dr. Wm. Collier.
 £12 12s.—Dr. P. H. Adams.

M. LAFERAN, a physician and pathologist whose discovery of the malarial parasite has made his name so well known, is succeeded as president of the Académie de Médecine, Paris, by M. Richelot, surgeon to the Pans Hospital. M. Bourquelot, professor of pharmacy in the School of Pharmacy of the University of Paris, has been elected vice-president, and according to the rules of the Académie will be president next year.

As the result of a report by Dr. Richard P. Strong, director of the League of the Red Cross Societies, the Spanish Red Cross has undertaken an antimalarial campaign in Spain under the direction of Professor Massimo Sella, assisted by Professor Giuseppe Pittaluga. The campaign will start in Camarea, which is the most malarial province in Spain.

SHORT LIFE TABLES.

MORE than seventy years ago Dr. Farr wrote as follows: "As it might be expected, from the similarity of the human organization, that all classes of men would, *ceteris paribus*, live on an average the same number of years, it becomes important to ascertain whether this be the case; and if it be not, to determine to what extent life is shortened in unfavourable circumstances. The life table answers this purpose; and is as indispensable in sanitary inquiries as the barometer or thermometer, and other instruments in physical research." When Farr wrote those words the life table as a statistical instrument was already of a respectable age, since to John Graunt and to Edmund Halley must be assigned the credit of its invention (Graunt had the idea, but Halley constructed the first table). But the vicissitudes of the life table through the eighteenth century were not such as to commend its use to the sanitarian, since most of the tables, including the most famous of English tables, were constructed on unsound principles, and one involved the nation in heavy pecuniary loss. Hence practical men, even if unable to point out the theoretical error, were alive to the incorrectness of the conclusions drawn. So far as concerns the commercial or insurance aspects of the problem, the earlier mistakes, particularly that of Dr. Price, who constructed the Northampton table virtually from a summation of deaths without allowance for the increase of population at risk, had been recognized and corrected before the time of Farr, but to Farr belongs the whole credit of adapting the life table method to the purposes of the medical profession.

After Farr's time there was little danger of a repetition of old mistakes in this matter by instructed students, although even now one occasionally meets with inferences drawn from a comparison of mean ages at death, the means having been deduced from deaths in a non-stationary population. The employment of the life table by sanitarians did not, however, become general. The reason was that the more correct method of construction was laborious and technical. To construct a rough life table from deaths (the old method) is extremely easy; provided the deaths are given at age intervals of a year, the construction merely involves a little elementary arithmetic. Unfortunately the result in a varying population is altogether misleading. If the population is increasing, we shall have too many deaths at early ages, since the deaths at older ages occur among the survivors of a smaller population, so that the mean age at death and expectation of life will be too low. If, as in the correct method, we take into consideration the census of the living, to build up the life table does not, indeed, demand a knowledge of very recondite mathematical processes, but it does involve some facility in the manipulation of uncouth algebraical formulae and a very great amount of arithmetical labour.

Dr. Farr was, of course, aware of this difficulty and devised a short method of constructing life tables, but the approximations to the true values were not very close, and his plan did not become generally recog-

nized. Several other short cuts have been proposed, one, discovered by Mr. George King and published in 1914 in the first part of the Supplement to the Seventy-fifth Annual Report of the Registrar-General, leaves little to be desired in point of accuracy, but is still perhaps somewhat formidable to the busy medical officer of health. The most valuable discovery, from the point of view of the medical officer of health, made in this field we owe to Dr. John Brownlee.¹ From the sanitary aspect, as Farr recognized in the quotation with which we began, the expectation of life is the "life table constant" which one chiefly desires to know. Now it should have been evident, but until pointed out by Dr. Brownlee it was not evident, that the expectation of life at any age must be some function of the population death rate at and above that age. Dr. Brownlee accordingly set to work to discover the form of the law and found it to be extremely simple. By the aid of the formulae he devised it was possible to calculate with little trouble the expectation of life at any age in a population respecting which the death rates at ages were known. Thus, to take an example, the true expectation of life of males (London, 1911-12) at age 20, as deduced by a complete method, was 42.35 years. Applying Dr. Brownlee's method to the crude data we reached, at the expense of half an hour's arithmetic, the figure 42.40. Without a mechanical calculator the time involved might have been as much as an hour.

Contemporaneously Dr. E. C. Snow was attacking the problem, and dealt with several other constants of the life table upon similar lines. The work naturally interested Sir Bernard Mallet, the Registrar-General, and Dr. T. H. C. Stevenson, whose work as Superintendent of Statistics at the General Register Office has justly earned him the highest praise to which a vital statistician can aspire—that of being a worthy successor to Dr. Farr. In the result, Dr. Snow's method was submitted to extensive tests in the General Register Office, and has now (after many years' delay occasioned by the war) been published as Part 2 of the Supplement to the Seventy-fifth Annual Report of the Registrar-General.²

The Blue Book contains not only a full and lucid explanation of Dr. Snow's method, with worked examples and tables which will greatly simplify the task of a computer, but also the deductions by the method of the chief life table constants for the administrative counties, the large county boroughs, and the larger rural and urban aggregates, based on the mortality experience of 1911-12. So rich a statistical feast has rarely been spread, even by the General Register Office. In discussing it, attention must of course be paid to the Registrar-General's preliminary caution: "The question how far the mortality disclosed in the years 1911 and 1912 represented the normal mortality of the district or how far it is, in fact, adversely abnormal by reason of any particular cause—for example, an epidemic—should be carefully considered." Attention must further be directed to the influence of errors of sampling upon the constants deduced from an analysis of the slender data yielded by sparsely populated areas. All these reserves being made, the contrast of different types of population is striking, if less glaring than those of the (incomparable) "mean ages at death," which daunted Chadwick. Let us, for instance, consider the expectation of life at age 20 of males computed by this method for typical areas. As instances of close aggregation and high industrialization we may take the County of London and the County Boroughs of Liverpool,

¹ Journ. of Hygiene, xiii, 1913, p. 178.

² Cmd. 1010, 1920. Price 1s. 6d. net.

Birmingham, and Sheffield. For these four great centres of industry the expectations of life of males at the age of 20 are 42.38 years, 38.48 years, 42.61 years, 41.65 years. Now let us choose four fairly populous non-industrial areas, namely, East Suffolk, Lincolnshire (Holland), Wiltshire, Oxfordshire. The figures are 47.94, 47.03, 47.07, 47.57.

It would not indeed be scientific to infer from such figures that the choice, or necessity, which determines a man to lead his life in an industrial centre rather than in the country is equivalent to an average sacrifice of from five to nine years' existence. A standard based upon other life table constants, perhaps upon the proportion of years lived between the ages of, say, 20 and 50, would be more suitable. Yet these figures are significant of much, decidedly more illuminating than those which led to the catchword of "a C3 population." We are now within sight of a real measure of the difference in terms of health separating a rural from an industrial population.

It is a pity that no similar comparison can be instituted for the one extinct polity which, like our own, had a highly developed industrial system associated with great cities. The external features of city life in Rome are well known, and Professor Frank, of Johns Hopkins University, has recently³ collected evidence showing that in certain industries, notably brickmaking and the manufacture of table ware, capitalist mass-production was highly developed by the end of the first century of our era. In 1913 that accomplished scholar and statistician, the late Dr. W. R. MacDonell, attempted to compute the expectation of life in different provinces of the Roman Empire, and concluded that there was an immense difference between Roman Italy and such provinces as Lusitania. Dr. MacDonell was, of course, obliged to compute his life tables from deaths only (his data were the inscriptions on tombs), so that his comparison with modern life tables may, to some extent, be vitiated by the error mentioned above. Yet the question is of high interest, since industry in the old civilizations was largely carried out by slave labour, and we wish to know how much of the contrast between town and country can be diminished by conscious effort and how much is beyond our means of control.

We are, however, straying from the path upon which we entered, and will conclude our journey with the expression of our gratitude to Dr. Snow, to Sir Bernard Mallet, and to Dr. Stevenson; the work they have carried out forms one of the most valuable contributions to vital statistics of recent years.

OPERATIONS ON TONSILS AND ADENOIDS IN OUTDOOR CLINICS.

We have published lately a considerable number of letters upon the risks and complications of operating on tonsils and adenoids in outdoor clinics. Attention has thus been focussed upon an important subject first raised in our issue of November 1st, 1919, by Mr. Douglas Drew, and brought to a head on December 11th, 1920, by Mr. E. Watson-Williams's article, from which arose the present correspondence.

Mr. E. Watson-Williams showed that the morbidity among children operated upon in the out-patient department of the Bristol Royal Infirmary was more than four times as great as among in-patients; among 239 out-patient cases, in 1919, he had had 10 cases of morbidity (that is, of more or less serious complications), and one death, directly traced to septic infection after the operation for tonsils

and adenoids; while among 100 in-patient cases in 1918-1920 (comprising those patients admitted because they did not appear robust, and a few cases in which submucous septal resection was done as well) there was only one instance of definite morbidity, and that of a much less serious kind than those recorded among the out-patients. Mr. Watson-Williams's out-patient cases, moreover, were carefully selected; no sickly child, and no child living outside Bristol itself, was included; the parents were given printed instructions for use before and after operation; the children were inspected before being sent home; the parents were directed to wrap them up well, not to allow them to walk a step, to keep them indoors for four days, and to bring them on the fifth and twelfth days afterwards for inspection; and antiseptic lozenges were prescribed. Measures on much the same lines are carried out in many other hospitals, and seem to be the best that can be done in the circumstances under which the surgeon, whose duty it is to perform such operations, has to do his work. It can hardly, however, be considered good surgical practice to leave without proper post-operative treatment, and often amidst bad surroundings, exposed to septic discharges, a raw wound of considerable size, such as is produced by this operation. Yet the choice for the surgeon at present lies between operating under such unsatisfactory conditions or not operating at all; and, on the whole, the gain to health by performing the operation is greater, taking the risks duly into consideration, than by not performing it.

In order to bring about any change there must be some unanimity in the medical profession, not only upon the best method of dealing with the children operated upon, but upon the seriousness with which the operation is to be regarded. The public and a large number of practitioners have come to look upon it as a trivial proceeding. This may partly be explained by the frequency of its performance—it is perhaps the commonest surgical operation done under general anaesthesia—and by the high degree of technical skill, the result of constant practice, displayed by throat surgeons in performing it. We are told, on the authority of Sir William Milligan and others, that some surgeons are known to perform the operation upon private patients at their consulting rooms, and to send them home by taxicab or by train a few hours later. In an operation in which, as has been pointed out by our correspondents, deaths from the anaesthetic are still too frequent, and such complications as acute otitis media, acute mastoiditis, bronchopneumonia, acute sepsis, glandular infection, and serious haemorrhage are not uncommon, this procedure would seem to be indefensible, the more so because the complications enumerated are almost unknown if the patient is kept in bed and properly nursed for two or three days after operation. The consensus of opinion among the leading authorities is that the operation should be regarded more seriously altogether, and that the patient should be admitted to hospital for at least forty-eight hours, as by that means the risk of morbidity can be almost eliminated.

The difficulty is that most hospital authorities are so circumstanced at present that they can hardly be asked to provide the necessary beds for the admission of patients after such operations, even for forty-eight hours. Nevertheless it may be pointed out that this has been done at Portsmouth Dye and Ear Hospital, and, to a modified extent, at Ancoats Hospital, Manchester. Local health authorities, on the other hand, have powers to make provision not only for the performance of this operation by payment of fees to the hospitals, as many of them do at present,

³ *An Economic History of Rome*, Baltimore, 1920.

but also to provide suitable places for the performance of the operation and beds for post-operative convalescence. If education committees through their medical officers take the responsibility of insisting on children being operated upon—sometimes in the face of opposition from the parents—they should, we agree with Sir William Milligan, provide beds at least for those whose homes are unsuitable for safe post-operative treatment. If the beds cannot be found in the voluntary hospitals they might perhaps be provided, as Dr. P. Watson-Williams has suggested, in the Poor Law hospitals, where clinics could be established in charge of surgeons experienced in this branch of surgery, and the guardians, as in other cases, could charge the relatives of the patients for maintenance and treatment in accordance with their means.

STUDIES IN CEREBRO-SPINAL FEVER.

Of the medical problems connected with the segregation of large bodies of men in camps for military training none was more alarming or more difficult of solution than that of cerebro-spinal fever, and the fact that the disease at no time affected large numbers of the population is eloquent of the effectiveness of the measures adopted for controlling it. The mysterious sporadic outbreaks of meningitis baffled explanation, and the high mortality attending them made a scientific therapy a matter of extreme urgency. No one, however, not conversant with the state of our knowledge of the causal agent can appreciate the immense amount of pure laboratory work necessary before therapeutic measures could even be started. It was easy enough to recognize the infecting organism in the spinal fluid of those affected, but quite a different problem to ascertain its mode of conveyance and the conditions under which it spread. It cannot yet be said that we know how it penetrates the outer defences of the body. A delicate organism to grow, it necessitated much experimentation for the elaboration of some special artificial medium particularly favourable to its growth, and its differentiation from several other similar bacteria found in the nasopharynx was neither sure nor easy. The preliminary investigations on these points by Dr. Mervyn Gordon and his collaborators were fruitful in results, and the War Office is to be congratulated not only on the promptitude with which it called in expert assistance but also on its choice of the bacteriologists. A former publication of the Medical Research Council (No. 3) dealing with the earlier part of the work is now out of print, but the more recent report¹ (No. 50) issued last year embraces practically all of it, and adds the later, and perhaps more important, essays in the preparation of curative serums. The present report, covering the four years' work, is arranged under three main divisions. The first part, mainly recapitulatory, deals with the state of our bacteriological knowledge when cerebro-spinal fever first broke out amongst the troops, and gives an account of the measures taken to cope with it—points with which most people are now familiar. The second part comprises studies on the serological differentiation of meningococci from other organisms and their classification into strains, on the nature of the endotoxin, and on antibody formation. Dr. Gordon's four types of meningococci are now universally known, and for the most part, in spite of much criticism by bacteriologists on relatively minor points, his work has received confirmation and has met with the appreciation which it fully deserves. Part III of the report deals with the application of these and other studies to the prevention and treatment of cerebro-spinal fever. A striking account is given of the way in which over-

crowding raises the percentage rate of carriers and how such a rise can certainly be taken as a premonitory sign of an approaching outbreak. By such careful observations the outbreak may possibly be entirely prevented or at any rate reduced to negligible proportions. Working with the knowledge obtained from the study of the different types of meningococci, Dr. Stanley Griffith at Cambridge succeeded in producing a very potent serum against the endotoxin of Type I, though less successful in the efforts to produce antitoxin against the other types. It is difficult to obtain a standard for comparison owing to the varying mortality of outbreaks, but, generally speaking, the use of curative serums was attended with much diminished death rate from the disease—a diminution of nearly 50 per cent. The most obvious success was obtained with Type I antiserum: a patient with meningitis due to organisms of this type was given nearly nine chances out of ten of escaping death. This report on cerebro-spinal fever is one of the best publications of the Medical Research Council, and will long remain the standard work on the subject and the foundation on which future investigations will be conducted. Much of it, no doubt, will appeal more to the bacteriologist than to the general practitioner, but the reading of it by anyone will show the magnitude of the problems that confronted Dr. Gordon and his band of fellow-workers and the high degree of success that attended their efforts.

PSYCHOTHERAPY.

To the current number of the *Edinburgh Review* Dr. William A. Brend contributes an article on psychotherapy and the experience which has been gained in the treatment of neurotic disorders resulting from the war. He traces briefly the development of the new psychology; he indicates the nature of the difference of outlook between the various schools of thought; he explains the principles upon which psycho-analytic methods are founded; he suggests the directions in which the application of these principles would seem to be of value; and he raises a timely note of warning against the indiscriminate and unnecessary use of psycho-analysis. The tone of the article is sympathetic, and it comprises a clear and balanced survey of a difficult subject, which will be found of value to the readers for whom it is intended. In commenting upon the advances which have been made in psychotherapy during recent years, Dr. Brend makes certain constructive suggestions as to future developments. He shows that the results of treatment at the clinics for nervous pensioners have been exceedingly gratifying, and he urges the necessity for the greater provision of similar treatment for the ordinary civilian population. That there are directions in which such provision is now being made Dr. Brend shows in his references to the Maudsley Hospital, in which very useful work in investigation and teaching is being carried out under the guidance of Sir Frederick Mott, to the courses of instruction provided at some of the larger hospitals, and to the establishment during recent years at some of the universities of diplomas in psychological medicine. In spite of these developments Dr. Brend urges that more provision is urgently necessary, and he raises a plea for the establishment, closely associated with a clinic, of a well-endowed central school for the teaching of psychotherapy. In emphasizing the need for voluntary financial help in this matter, the views of Dr. Brend are in accord with those expressed by others who are interested in the same question. Dr. E. Goodall, of Cardiff, who has taken an active part in the development of psychiatric clinics, has on more than one occasion emphasized the necessity for support from wealthy members of the community, and it is particularly interesting to note that Professor Kraepelin of Munich has recently shown that State aid does not suffice to meet the needs of the case.²

¹ Special Report (No. 50) of the Medical Research Council. Cerebro-spinal Fever: Studies in the Bacteriology, Preventive Control, and Specific Treatment of Cerebro-spinal Fever among the Military Forces, 1915-1919.

² Professor Emil Kraepelin: The German Institute of Psychiatric Research, *Journal of Nervous and Mental Diseases*, June, 1920.

In giving an account of the Psychiatric Institute at Munich, the famous German psychiatrist shows that more money is needed for a research institute on a large scale, and that the State, hampered as it is by financial difficulties, cannot be counted upon to provide this. He suggests, also, that this method of founding institutions is possibly better for their healthy growth, as it gives them greater latitude. The suggestion is of the more interest since it comes from within the Reich, where university and other educational institutes have been accustomed to rely on State aid. We would express the hope, should the rich benefactor be found, that an institute of this kind would not confine its aims to the teaching of psychotherapy, but that it would enlarge its scope to include all the manifold problems of mental disorder.

VIENNA AND LONDON.

LAST September Dr. George E. MacLean, Director of the British Division of the American University Union in Europe, addressed a letter to this JOURNAL stating that he had been informed by a young physician from one of the Middle Western States of the United States that a committee in Chicago was circularizing physicians in his State, saying that an excursion had been organized for physicians to Vienna for study, as before the war American physicians were accustomed to do. The Chicago committee gave assurances that the way had been prepared for the reception of these medical men in Vienna. We have now received a letter, dated January 15th, from Professor Wenckebach, director of the first medical university clinic in Vienna, stating that neither the Viennese medical faculty nor the official organization for post-graduate courses know anything of this propaganda. He encloses a programme of the first official course of lectures which will be given in Vienna next month; it extends over a fortnight, and is confined to internal medicine. The lectures will be given by the professors of the Vienna medical school, and each will deal with a subject to which he has given special attention; at the opening course on February 7th Professor Wenckebach will speak on cardiac insufficiency and on the value of quinine in that condition. On the same day Professor Winterberg will give a demonstration of the value of the electro-cardiograph in diagnosis. On February 8th Professor Pal will deal with arterial sclerosis; on February 9th Professor Falta with nephritis, and so on day by day until February 19th, when Professor Economo will lecture on encephalitis. The fee for the course is to Austrians, Hungarians and Poles, 200 k., to Germans, Czecho-Slovaks, Bulgarians, and Armenians 500 k., and to persons of other nations, 1,000 k. It is proposed to arrange other courses in June and December. Further particulars can be obtained from the office of the *Wiener medizinische Wochenschrift*, Wien, IX, Porzellangasse 22, when help in finding lodgings will be given. In a previous article it was stated that we were informed that the invitations issued by the American committee were accompanied by assurances of plenty of food and comfortable accommodation. On this point Professor Wenckebach tells us that, as a matter of fact, a foreigner coming with any sort of sound money will be in a position to live in Vienna quite cheaply and to get everything he wants at a price low for him. "At the same time," he states, "all the good things of life are out of reach for the Vienna people itself, because it is absolutely unable to gain enough crowns for paying such prices. The fee of a thousand crowns would mean for an Englishman something like five shillings." Professor Wenckebach goes on to suggest that it might be possible to arrange some co-operation between Vienna and London in respect of post-graduate study. The position in London, where the work of the Fellowship of Medicine and Post-Graduate Medical Association continues, is unchanged at present, but it is to be hoped and expected that the inquiries of the committee on post-graduate education just appointed by the Ministry of Health will contribute towards a satisfactory outcome.

EXPERIMENTAL INFECTION WITH LEPTOSPIRA ICTEROIDES.

IN the twelfth instalment of his researches in connexion with the etiology of yellow fever Noguchi¹ reports the results of experiments to show how *Leptospira icteroides*, the causal organism he has isolated and named, reacts to salvarsan and neo-salvarsan, both *in vitro* and in the animal body, and also to salvarsanized serum. In addition an interesting comparison is drawn between the action of these arsenical preparations and that of anti-icteroides immune serum upon *Leptospira icteroides* in experimental infections and *in vitro*. Much interest attaches to the way in which *Leptospira icteroides* is affected by salvarsan preparations, as it was found by Inada and Ido, and by Noguchi in some unpublished observations made in 1917, that infections with the closely allied *Leptospira icterohaemorrhagiae*, the exciting cause of spirochaetosis icterohaemorrhagica, are not therapeutically influenced by these drugs, and that there is thus a difference from infections with other genera of the Spirochaetoidae. Experiments now published by Noguchi show that from the therapeutic standpoint the salvarsan preparations are not of any value in experimental infection of guinea-pigs with *Leptospira icteroides*. Several series of test-tube experiments made to determine the direct effect of salvarsan and neo-salvarsan on this organism showed that these drugs exert a slow but highly poisonous influence on the leptospira, a culture of which is killed in twenty-four hours by salvarsan in dilutions of 1 in 20,000. The discrepancy between the absence of any effect *in vivo* and the destructive influence *in vitro* of salvarsan on the leptospira suggested an investigation of the action of salvarsanized serum; in serums from rabbits that received intravenously 0.05 gram of salvarsan or neo-salvarsan per kilo of body weight before bleeding, the leptospira remained active for at least an hour, but became somewhat sluggish after eighteen hours, and were all dead and degenerated in forty-eight hours, whereas leptospira mixed with normal rabbit's serum lived and multiplied. Comparison of the time (twenty-four hours) that salvarsan *in vitro* takes to kill the leptospira with the time (forty-eight hours) taken by salvarsanized serum to produce the same result shows that the action of these drugs is slower after passage through the animal than it was before. From this the important deduction follows that if this phenomenon were also to take place in the infected body injected with these drugs, it is clear that in a rapidly evolving infectious disease like yellow fever the progress of the infection will be too rapid to allow the drugs to exert their beneficial effect upon the course of the disease. In direct contrast to the behaviour of salvarsan preparations *in vivo* and *in vitro* is the action of anti-icteroides immune horse serum, which, in a dose of 0.0001 c.cm., or 1 c.cm. of 1 in 10,000 dilution, protected guinea-pigs from an infection with at least 5,000 minimum lethal doses of *S. icteroides* when injected simultaneously; but the same serum failed to have any harmful effect when mixed *in vitro* in a concentration weaker than 1 in 2,000. Rapid disintegration of the leptospira occurred in a concentration of 1 in 20, and almost complete agglutination and degeneration with 1 in 200 concentration. The contrast between chemo-therapy, as carried out with salvarsan preparations, and sero-therapy apparently has considerable practical significance.

THE REGISTRAR-GENERAL'S REPORT FOR 1919.

THE eighty-second annual report of the Registrar-General of births, deaths, and marriages in England and Wales has just been issued as a Blue Book of 520 pages.² The salient features of the vital statistics of 1919 are summarized by Sir Bernard Mallet in his prefatory letter, dated November, 1920, and addressed to the Minister of

¹ H. Noguchi, *Journ. Exper. Med.*, Baltimore, 1920, xxvii, 381-400.

² To be purchased through any bookseller or directly from H.M. Stationery Office. (Cmd. 1017. 7s. net.)

Health. The marriage rate was 19.7 per 1,000; this was the highest on record, and the provisional figures for 1920 indicate a further rise. The birth rate was 18.5 per 1,000, being 0.8 per 1,000 above that recorded for 1918, but 5.3 below that for 1914, which, particularly so far as the birth rate is concerned, may be regarded as the last year unaffected by war conditions. The death rate was 13.7 per 1,000, being, with two exceptions, the lowest on record, notwithstanding the heavy mortality from influenza in the early part of the year. Infant mortality was 89 per 1,000 births, being the lowest rate hitherto recorded, though when allowance is made for a falling or rising birth rate, the rate for 1916 appears to have equalled it. The provisional figures for 1920, printed at p. 178, indicate a further fall, both in the general death rate and in infant mortality. As in other recent reports the mortality of infancy and early childhood is examined in special detail. The death rates from measles, whooping-cough, and enteric fever were by far the lowest on record; on the other hand, deaths from small-pox were more numerous than in any year since 1905. Notwithstanding the influenza epidemic, the mortality from tuberculosis was the lowest on record, and that from pneumonia normal. The deaths from cancer were in accordance with the general movement of cancer mortality in recent years, which has increased much faster among males than females, though for several years before 1919 this increase seemed to have been arrested for both sexes. Cancer, however, forms the one great exception to the general tendency for mortality at most ages to decline. The Registrar-General dwells upon the difficulty of making local estimates of population; this always increases as the last census becomes more distant, and the possibility of error was much aggravated by the movement of population caused by the war. We conclude this brief notice of a great statistical work by observing that the estimated total population in England and Wales in the year under review was 36,800,000, amongst whom the females exceeded the males by as much as 2,438,690. Of the men some 800,000 were estimated to be non-civilians.

OUTBREAKS OF FOOD POISONING.

THE Ministry of Health is anxious to obtain early information, as exact as possible, on all cases of food poisoning. It has therefore requested all medical officers of health to notify the Ministry at the earliest possible stage whenever they have reason to suspect that any death or outbreak of illness in their districts is due to food poisoning. Although neither medical practitioners nor the general public are under any statutory obligation to report cases of food poisoning to the medical officer of health, it is hoped that they will co-operate with a view to safeguarding the public health in this direction, the local health authority being prepared now to authorize any necessary inquiries and investigations—bacteriological, chemical, and otherwise—into the possible causes of an outbreak of suspected food poisoning. The chief causes of food poisoning are: the contamination of foods by inorganic poisons (for example, arsenic, antimony, copper, and lead), and bacterial contaminations, the latter being of much more frequent occurrence, especially in the case of foods of animal origin. Care should be taken to secure samples from all available food materials in cases of food poisoning, apart from those to which suspicion attaches at first sight, as it often happens that a food substance which was not suspected in the first instance is ultimately proved to be the material at fault, especially when the illness is suspected to be due to an inorganic poison. The complete history of each case should be obtained with the least possible delay, as the determination of the circumstances in which food poisoning has occurred often turns upon the elucidation of apparently trivial points, and after some days' interval it is impossible to rely on recollection of them. In addition to the examination of samples of suspected food materials, it

is of importance that bacteriological examination should be made of materials from persons affected and particularly of the organs of fatal cases. The exact material required may vary in individual outbreaks, and in all such cases the medical officer of health concerned should consult the bacteriologist entrusted with the examination. His advice should also be obtained in order that the material may be transmitted with proper precautions and in a condition suitable for examination. The serological reaction of the blood of persons attacked, the Ministry emphasizes, should always be bacteriologically investigated.

THE CASE OF DR. DOLLING.

DURING its last session the General Medical Council discussed very fully the case of Dr. Charles Edward Dolling, who was reported to the Council as having been convicted of a misdemeanour at the Westminster Police Court. The magistrate's decision was upheld on appeal at the general Quarter Sessions. As will be seen from the report published in the SUPPLEMENT of December 4th, 1920, p. 155, the case was heard in private; the result was that the General Medical Council decided that Dr. Dolling's name should not be removed from the *Medical Register*. The Council considered the matter *in camera*, but its decision, which we understand was unanimous, shows that it accepted without hesitation Dr. Dolling's version of the facts and circumstances leading up to his conviction, and also accepted the unimpeachable testimony as to character that Dr. Dolling produced. As a member of the medical profession, therefore, Dr. Dolling's character is clear, but he held a commission in the Royal Army Medical Corps. He had been in practice in Adelaide, came to England in 1915, and served continuously until October, 1919. We have examined the papers submitted to us by Messrs. Hempsons, the solicitors who represented Dr. Dolling before the General Medical Council, and agree that there has been a grave miscarriage of justice in the courts, owing, probably, to the imperfect manner in which Dr. Dolling's case was originally stated. The only course open to Dr. Dolling is to appeal for a pardon. This appeal is now being prepared, and if successful will render it possible for him to be reinstated in the army.

HOSPITAL INQUIRY COMMITTEE.

THE Marquess of Linlithgow has been appointed, on the nomination of the Secretary for Scotland, to the Committee on the Finances of Voluntary Hospitals appointed by the Minister of Health, and Sir W. B. Peat, of the firm of W. B. Peat and Co., chartered accountants, has been added to the Committee. The composition of the Committee is now therefore complete. It consists of Lord Cave (chairman), Lord Linlithgow, Sir Clarendon Hyde, Sir W. B. Peat, Mr. R. C. Norman, and Mr. Vernon Hartshorn, with Mr. L. G. Brock, of the Ministry of Health, as secretary. Its terms of reference are: "To consider the present financial position of the voluntary hospitals and to make recommendations as to any action which should be taken to assist them." The first full meeting of the Committee was held on Wednesday, January 26th, when evidence was given in the morning by the Hon. Sir Arthur Stanley, Chairman of the British Red Cross Society and Treasurer of St. Thomas's Hospital, and Sir Napier Burnett, Director of Hospital Services under the British Red Cross; and in the afternoon by Viscount Knutsford, Chairman, and Mr. E. W. Morris, House Governor, of the London Hospital.

COMMITTEE ON POST-GRADUATE EDUCATION.

WE understand that the Ministry of Health has appointed a committee to inquire into the position with regard to post-graduate medical education and to report on the steps which the Ministry should take to assist in placing it on a satisfactory basis. The Earl of Athlone, chairman of the Middlesex Hospital, has been appointed chairman of

the committee. The other members of the committee are, we believe, all members of the medical profession, and are representative of the Ministry, of the medical schools, and of the profession generally. In our view it has been shown, that for an efficient post-graduate medical school in London a large general hospital will be needed to serve as a central office and meeting place, and for certain types of instruction. Events have proved that to achieve this end a parliamentary subsidy will be necessary.

FEES OF PUBLIC VACCINATORS.

THE minimum fees for domiciliary vaccination are at present precisely the same as they were from 1899 to 1907. From 1907 to 1919, it may be recalled, there was actually a reduction in the minimum fees, in spite of protest on the part of the public vaccinators and of the fact that this was directly at variance with the recommendation of the Departmental Committee of the Local Government Board—a state of affairs which, in view of the greatly increased expense in every department of medical practice, ought not to exist. The Ministry of Health, in the Order of 1919, admittedly removed a grievance of many years' standing, but hardly went far enough, leaving to the boards of guardians themselves the opportunity of making such increases upon the minimum as should be justified by the altered circumstances of the times. The Association of Public Vaccinators has accordingly addressed a circular letter to every board of guardians in England and Wales, pointing out these facts; but this letter, to be of any real advantage, should be followed up by direct application for increased fees, addressed to the individual boards of guardians by every public vaccinator in the country.

THE Hunterian Oration before the Royal College of Surgeons of England will be delivered by Sir Charters J. Symonds, K.B.E., C.B., in the theatre of the College, Lincoln's Inn Fields, on Monday, February 14th, at 4 o'clock.

THE following lectures will be delivered at the Royal College of Physicians of London, Pall Mall East, on Tuesdays and Thursdays, at 5 o'clock: Milroy Lectures—Dr. Martin Flack: Respiratory Efficiency in Relation to Health and Disease, February 17th, 22nd, and 24th. Goulstonian Lectures—Dr. George Graham: Glycaemia and Glycosuria, March 1st, 3rd, and 8th. Lumleian Lectures—Dr. A. Whitfield: Some Points in the Etiology of Skin Diseases, March 10th, 15th, and 17th.

PRESENTATION TO DR. J. A. MACDONALD.

THE following further subscriptions have been received from January 1st to January 24th, 1921, in response to the appeal published in the JOURNAL of July 24th (p. 129), towards a presentation to Dr. J. A. Macdonald on the occasion of his retirement from the office of Chairman of Council of the British Medical Association which he had held for ten years. Subscriptions of any amount not exceeding five guineas should be made payable to "The Macdonald Presentation," and sent to the Medical Secretary, British Medical Association, 429, Strand, London, W.C.2.

WILLESDEN MUNICIPAL CLINICS AND HOSPITAL.

SIR,—The situation which has arisen in Willesden calls for energetic action on the part of every Division and Branch in the country. The medical activities of the Health Committee of the Urban District Council threaten to take away nearly all the work of the general practitioner, and possibly also of the consultant, both among mothers and among children up to the age of 14 years now, and ultimately to the end of school life.

May I ask every honorary secretary to consider carefully the following:

1. Each Division of the British Medical Association should carefully examine the annual reports of the medical officers of health in its area at an early date and report at once to its Branch Council or to Dr. Cox any evidence of undue encroachment upon the work of the general practitioner or the consultant.

2. As many practitioners are unfamiliar with the work of the various medical officers of the various authorities, and the relations between these and practitioners are not always so good as they might be, Divisions should arrange meetings to be addressed by these officers, at which their work could be explained and discussed. Begin with the M.O.H., follow with resident medical officers of the isolation hospital, infirmary, and hospitals in the area, medical officers of welfare, school, and tuberculosis clinics, referees to the Pensions Committee, and the National Health Insurance referees.

3. Divisions should consider the formation of a Local Medical Advisory Council (Dawson Report), and in the meantime should appoint a special committee to watch and report on the medical activities of the various authorities.

4. Each Division should invite at least a portion of its non-members to every medico-political meeting, and should consider the advisability of appointing an honorary organizing secretary, whose duty would be to call on non-members, find out their grievances, and induce them to join the Association. The larger the percentage of members and the more non-members are invited to meetings the better can the Division claim to represent the profession in dealing with local authorities and with the Ministry of Health.

5. Larger Divisions should consider whether they could not do better work if divided up into areas, or into new Divisions corresponding to the areas of the local authorities.

We asked for a Ministry of Health, and we have got it. What it is going to be will depend largely on what we try to make it. Now is the time to insist that the family doctor shall receive every encouragement, and to back up Sir George Newman in his opposition to a State medical service, in which I presume he includes a whole-time municipal service.

Doubtless most of us, if we were M.O.H.'s, thinking chiefly of administrative difficulties, would do as the M.O.H. of Willesden proposes; but may I urge him to allow his breadth of vision and his prophetic instincts to come into play equally with his administrative abilities? At present his Health Committee seems to be following a course which must prove disastrous to the profession and ultimately to the public.—I am, etc.,

WILLIAM PATERSON, M.B., Ch.B. Edin.,
Honorary Secretary, Willesden Division.

London, N.W., Jan. 21st.

THE BRADFORD MUNICIPAL GENERAL HOSPITAL.

SIR,—In the JOURNAL of January 15th Mr. Basil Hall of Bradford informed the medical profession that the Bradford Municipal General Hospital "remains the same old obsolete group of buildings which the Local Government Board condemned as unfit for hospital purposes twenty years ago."

Having been intimately connected with the hospital in question for nearly that length of time, I can only suppose Mr. Hall to be either woefully ignorant or wilfully deluded.

In the first place, the Local Government Board has

never condemned any portion of the present hospital buildings, although one block was condemned by me sixteen years ago and was swept away last year. On the other hand, three modern hospital buildings were completed sixteen years ago, having a first-class operating theatre and accommodation respectively for 156 adults, 80 children, and 45 maternity cases. These new hospital buildings compare favourably with any in the country, and I cordially invite Mr. Hall to revisit them and refresh his memory.

In addition, and within the last four years, three other pavilions have been erected and put into use, each accommodating 100 patients. Thus, at any rate, we have 581 beds to which the expression "same old obsolete" hardly seems to apply. Nor is it any more applicable to the medical and surgical equipment of these or of the other and older wards of the hospital.

Mr. Hall says he would welcome "real co-operation" between the Bradford Royal Infirmary and Municipal Hospital. One of the prime essentials of real co-operation being mutual knowledge, I trust the above facts will be of use. I am afraid, though, that Mr. Hall's idea of co-operation in this case implies the conversion of St. Luke's, with its splendid wards and equipment, into a dump, on to which the Infirmary could shoo its patients after giving them the more exciting portions of their surgical treatment. This would make less risky than it is at present the well known procedure by which has been attained the new boast: "*There is at present no waiting list at the Infirmary.*"—I am, etc.,

B. HOLROYD SLATER,
Medical Superintendent, Bradford Municipal
General Hospital.

Bradford, Jan. 18th.

PROGNOSIS IN ENCEPHALITIS LETHARGICA.

SIR,—In view of the notice which the disease is now receiving, I am authorized by Sir George Newman to send a brief note on its prognosis so far as it appears from the collection of case reports made by me at the Ministry of Health.

A study of these reports, together with an examination of several old cases, shows that in many instances the later stages of the disease may be very prolonged and the source of much anxiety both to the patient and to his medical attendant. Facial and ocular palsies, marked paresis, and sometimes paralysis, of a limb or limbs, and tremors in the parts so affected, are constantly mentioned as existing after the patient has resumed or partially resumed his normal occupation. In addition, the higher faculties are apt to remain for some time distinctly impaired, so that loss of memory, defects of speech, mental lethargy, and a general loss of intellectual tone result. The character, too, not uncommonly becomes changed, and often for the worse, especially in children. It may be noted in passing that MM. Harrier and Levaditi in a recent paper (*Bull. et Mém. Soc. Méd. des Hôp. de Paris*, December 9th, 1920) support the conclusion reached by Marary—namely, that the sequelae of epidemic encephalitis are often no more than the symptoms of a form of the disease with a prolonged evolution.

It will be recalled that soon after the disease appeared in this country, and prior to January 1st, 1919, when encephalitis lethargica became a notifiable disease under the Public Health (Acute Encephalitis Lethargica and Acute Polio-encephalitis) Regulations, 1918, a special inquiry was initiated by the Ministry with the object of gaining information concerning the epidemiology and clinical characters of the disease. The material for investigation and the knowledge then available were both limited, but a full and carefully compiled report on the subject was issued by the Local Government Board in 1918.¹

At the time this report was issued the conclusions reached concerning the full course of the disease in individual cases and the ultimate fate of its victims were necessarily guarded and provisional in character. The mortality rate, for instance, in Dr. MacNalty's series of 168 cases worked out at approximately 22 per cent. Of the 541 cases of encephalitis lethargica notified during 1919 from England and Wales no less than 286 proved fatal, a mortality of 54.6 per cent. A later review of this

series resulted in the elimination of a certain number of fatal cases by reason of mistaken diagnoses, but even so the death-rate figure remained at 50 per cent.—a mortality which is probably much higher than is generally supposed. The fatality is greatest in those over the age of 30.

I may add, in view of a comment in your leading article of January 15th, that the Ministry of Health, in conjunction with the Medical Research Council, are actively continuing the investigation of this disease in its epidemiological, clinical, and pathological aspects. This co-ordination has already resulted in the successful transmission of the virus of encephalitis lethargica to monkeys in the Derby case, which was reported in the annual report of the Chief Medical Officer of the Ministry for 1919-20. The detailed information regarding notified cases which we are receiving from the medical staff of institutions, medical practitioners, and medical officers of health is proving of great value, not only as material for ultimate tabulation, but as a guide to the selection of cases for special investigation.

Possibly some of your readers can supply information on the after-history of cases notified during 1919, supplementary to that which they have already sent in reply to schedules of inquiry. Any such information would be specially welcome.—I am, etc.,

ALLAN C. PARSONS,
Medical Officer, Ministry of Health.

Whitehall, S.W., Jan. 24th.

X-RAY RADIATION AND CANCER.

SIR,—Mr. Sampson Handley's important lecture and the letters in the last issue of the *BRITISH MEDICAL JOURNAL* raise a question that is likely to claim a more or less rapidly increasing attention on the part of the profession. Dr. Lord's criticisms on the absence of any uniform or satisfactory method of x-ray dosage as applied to these cases are well founded, and probably none deplore this more than radiologists themselves. Until quite recently at least, the difficulties surrounding the problem have been very great. Such methods as have been devised have not proved satisfactory in practice, chiefly for the lack of standardization in the various parts of our x-ray equipment, all, or nearly all, of them difficult to standardize.

As to the potential value of radiation in malignant disease, this is no longer a matter for argument. Up to the present, even if the proportion of successful cases has been small, it is at least enough to prove we are on the right road. For several years past I have felt sure that radiation would be more likely to provide the much desired "cure for cancer" than anything else within our present knowledge. Given a suitable type and intensity of radiation there is no reason in theory why any localized malignant growth should not be made to disappear, whether it be superficial or deeply seated. Where we have failed in the past it is chiefly from unsuitable and insufficient dosage. Working with the most highly penetrating rays available, the loss of total radiation between the surface of the skin and a depth of 10 cm. below has been something in the neighbourhood of 90 per cent., more rather than less. At the present time, with one single exception, every x-ray set in the United Kingdom produces a type of radiation that is not sufficiently near the hard gamma rays of radium in character, and not sufficiently homogeneous to be of any real practical value in the treatment of malignant lesions of the more deeply seated parts.

Uniformly successful irradiation under these circumstances is possible only with x-ray tubes having a resistance equivalent to at least 16" of air, in conjunction with a filter thick enough to make the resultant radiation homogeneous. Few radiologists here use filters exceeding 6 mm. of aluminium, whereas to get homogeneous rays with a "gas" tube at least 12 mm. are necessary, and more with the Coolidge tube, since it gives a less homogeneous radiation than the best type of gas tube with water cooled electrodes. The American Coolidge tube is unsuitable for this class of work owing to the inadequate distance between the electrodes.

Quite recently it was my good fortune to spend a week in the university town of Erlangen, Bavaria, attending several hours daily in the *Frauenklinik*, under the charge of Professors Seitz and Wintz. The x-ray technique there practised is probably the most efficient in existence, and is

¹ Report of an Inquiry into an Obscure Disease (Encephalitis Lethargica, New Series, No. 121).

due to the efforts of Professor Wintz and his assistants. Not the least interesting fact is that this highly successful system has been evolved not by a radiologist, but by a gynaecologist, who was profoundly dissatisfied with the results of surgery in that class of malignant cases that come under the notice of the gynaecologist, including mammary carcinoma. One outstanding feature of the system is the method of dosage.

Special apparatus and tubes have been designed to give a type of radiation having qualities of penetration and intensity combined such as has been hitherto unattainable, with facilities for reproducing this standard type of radiation at will. Dosage thus becomes a matter of calculation and time, and the results are uniform and successful to a degree that would be surprising were it not quite in keeping with theoretical considerations. Empiricism is almost entirely absent in the matter of dosage, and after a tube has been standardized by instrumental means its radiation value is checked by biological methods before being put into practical use. Moreover, every tube is recalibrated at regular intervals. It is unnecessary to go into further technical matters, but I may be allowed to refer to some more details regarding dosage. Working under the standard conditions it is found that with the proper filter, focal-skin distance, etc., the maximum dose the skin will stand without serious injury will be given in about thirty-five minutes. This will be followed by reddening of the skin in about a week and tanning in about three weeks after, but no ulceration or other destruction of tissue. This is what is called the unit skin dose. Taking this unit skin dose as 100, it has been found that a cancer cell requires 110 per cent. of this to ensure its destruction; less may do so, but the dose must not be under 90 per cent. A dose of 70 per cent. to 90 per cent. will paralyse a cancer cell, so to speak, but it is not certainly destroyed, and may recover. If, however, a dose of only 40 per cent. of the unit skin dose is given to a cancerous growth, the latter is stimulated, causing it to increase rapidly, with serious, possibly fatal, results. Herein lies the explanation of some of our failures in the past. In our relatively feeble efforts to cure our patients we have attained this "vile" dose, hastening the very end we were doing our best to avert.

In view of these facts—and I have satisfied myself at least that they are substantially correct—a little consideration will show that our methods will have to undergo considerable modification if we are to ensure the degree of success we aim at. Supposing we are dealing with a case of uterine cancer, it is found that when we apply the unit skin dose to the skin over the symphysis only 18 per cent.—approximately—reaches the cervix, dispersion and absorption accounting for a loss of 82 per cent. Consequently we must use at least six ports of entry, all accurately directed towards the growth, if we are to ensure success, and these six doses must be given on the same day. The parametria will have to be similarly treated at intervals of eight and sixteen weeks respectively, such intervals being necessary to allow the blood and tissues to recover. In dealing with mammary and other relatively superficial cancerous growths we are limited practically to one port of entry and our technique has to be modified. The only method of getting even irradiation throughout a superficial growth is to set the tube some distance away—anything from 70 cm. to 100 cm., according to circumstances. Naturally this involves a serious loss by dispersion that can be made up only by a prolonged exposure which may be from five to ten hours or even more. This no doubt sounds formidable and to many may seem difficult, but it is not only practicable but successful. To go further into details would serve no useful purpose just now, and I shall conclude by giving some figures relating to results attained in the Frauenklinik at Erlangen, that give cause for serious reflection. I have been satisfied as to their substantial correctness, and I would ask those who may be disposed to question them to bear in mind that I have been there to investigate for myself, and that the type of radiation and the technique employed are entirely different from anything that has been done in this country up to the present. It will be assumed, of course, that cases in which dissemination had begun were not treated if there was any evidence of this fact.

In the year 1918 twenty-four cases of uterine cancer, with more or less involvement of the parametria, were treated with the x rays alone. At the present moment twenty of these are quite well and leading normal lives, being at least clinically cured. In some, fragments of suspicious-looking tissue were removed for microscopic examination, with negative results. In one case the treatment had no appreciable effect, for reasons that are not clear. In the other three dissemination had begun, though there was no evidence of this at the time. The primary lesions disappeared, but the patients died from distant

extensions. Turning to mammary cancer we find that exactly 75 per cent. of such cases treated in 1917 by the x rays alone are now clinically cured.

With the constant improvement in equipment and technique better results are expected for subsequent years, but that even these results can be attained by means of the x rays alone is sufficiently remarkable to give rise to a conjecture that our present methods of dealing with malignant disease are likely to undergo considerable modification in the near future.—I am, etc.,

London, W., Jan. 22nd.

REGINALD MORTON.

INFECTION OF THE SUPRACLAVICULAR REGION IN CANCER OF THE BREAST.

SIR,—I have been very interested in the letter of Mr. Parry published in the JOURNAL of January 15th (p. 99), relating his experience of the frequency with which, when operating for cancer of the breast, he found the glands above the clavicle revealed, on microscopic examination, evidence of cancerous infection. I have, in operating for cancer of the breast, for more than twelve years as a routine practice removed the fatty tissue, and contained glands, from the supraclavicular region, following the practice of some of the American surgeons, as although I recognized that it was not common to find cancerous glands there, yet occasionally they were discovered on opening up the supraclavicular space, though there was no evidence of their presence before operation. The supraclavicular extension of the operation was carried out in all cases except those in which it seemed desirable to shorten the time of the operation for some definite reason, or the primary growth was exceptionally small, and the axillary glands were not found to be involved at the operation. In the cases in which it was carried out it did not materially add to the risk of the operation. If we find in the supraclavicular region cancerous glands, of some size, which have to be removed from under the sterno-mastoid, and are in intimate relation with, or even adherent to, the internal jugular vein, and other important structures at the root of the neck, then removal does, of course, involve a very definite increase of risk, but I am now writing of an extension of the breast operation, which consists in clearing out the fat of the supraclavicular region, and all contained small glands, of the same nature as the routine removal of the axillary fat and glands.

Since reading Mr. Parry's letter I have looked through my records of operation for cancer of the breast from July, 1908, to October, 1911 (three years and three months), and in that period I find I operated on 38 cases. From these we must deduct 8, as in 4 cases the supraclavicular extension of the operation was not performed and in 4 cases glands could be felt above the clavicle before operation. Out of the remaining 30 cases, in only 3 did I find cancerous growth above the clavicle; in most of the cases in which there was no supraclavicular cancerous growth there was cancerous growth in the axillary glands, and in a few quite extensive growth, certainly in one case reaching up above the upper border of the pectoralis minor. But though it is evident that cancerous growth, at least as judged by naked-eye inspection, is not common above the clavicle, yet it is evident that in one case in ten, if I had not as a routine practice cleared out the supraclavicular tissue, I should have left nodules of growth there, and as this extension of the operation to the supraclavicular region involves no material risk, it does seem to me that it should be carried out as a routine practice, except in cases in which for some special reason it is contraindicated. Of course it may be that the small glands I frequently removed with the supraclavicular fatty tissue would, if they had been examined microscopically, have shown evidence of cancerous infection, as the glands Mr. Parry removed did, but I do not think they would. My experience is that one more often finds that a gland one is suspicious may contain secondary growth, is not found on microscopic examination to do so. I cannot say that in the three cases in which I did find nodules of growth or infected glands above the clavicle, those nodules were microscopically examined, but they were absolutely typical to the naked eye.—I am, etc.,

Bristol, Jan. 23rd.

CHARLES A. MORTON.

RISKS AFTER OPERATION ON TONSILS AND ADENOIDS IN OUTDOOR CLINICS.

SIR,—The paper of Mr. E. Watson-Williams, bringing forward the risks and increased morbidity following this method of treatment, deserves the thanks of the profession and public. The correspondence since the publication of this article shows that there is a general agreement as to the unsatisfactory manner in which this work is carried on.

Although I no longer practise this work, I accede to a request to give my opinions on the subject, for I have long felt that it was highly unsatisfactory. After some years I eventually abandoned the out-patient treatment of these cases and only operated on such as could be admitted to the wards, although a large number still continued to be dealt with in the out-patient department.

It seems to me that these hospital patients should have the same facilities that we demand for private patients, first, because it is safer, and any complication, such as reactionary hæmorrhage, can be dealt with readily by the surgeon or his assistants, and, secondly, because it is more humane. The recovery room after such a morning's work as usually obtains in most hospitals performing this type of work is a sight which no one with reasonable compassion can bear to witness. Add to this the preliminary starvation, the horrors of the operating theatre, and the aforesaid room, together with perhaps a tram or train journey afterwards, should make any one pause before countenancing such operations. I speak from personal experience of this method, and it would need a much more facile pen than my own to describe the feelings of a train journey after such an operation. Of course, it may be the lesser of two evils to operate under such conditions rather than not operate at all, but I have remarked on many occasions that were our patients perhaps something less than human we should have probably more humane means of dealing with them. I have also often wondered what an inspector of the N.S.P.C.C. would think could be present during a morning's work!

Our present hospital system, or perhaps rather the want of it, is at the root of the matter, for the poor voluntary hospitals are no doubt doing their best to cope with the large amount of work thrown on to them by the various Government inspecting agencies. It is to be hoped that this matter, which has been ventilated before, may now be settled, so that the better and more humane method may become the established one.—I am, etc.,

Newcastle-on-Tyne, Jan. 24th.

F. C. PYBUS.

SIR,—As Dick Phenyl remarks in *Sweet Lavender*, "Blame, blame, but never a word of praise." Surely one may be allowed to put in a mild and deprecatory protest on behalf of the methods of those of us, not eminent otologists, who week by week have the duty of dealing, as out-patients, with large numbers of children seriously handicapped by adenoids and enlarged tonsils.

At a time when railway bookstalls are pushing the sale of a book by a physician who undertakes to prove that operations on the throat are harmful and unnecessary, is it wise for medical men to join in a loud chorus of condemnation of present procedure, and even to suggest the issue of an appeal to the lay press in popular language? Is it not a fact that the alleged dangers of outdoor clinic treatment have been shown by experience not to be so very great after all? Are not fatalities known in the houses of the rich even when the patients are surrounded by the greatest precautions against disaster, and do no complications ever occur in well appointed nursing homes? At the London County Council school treatment centres printed directions as to treatment before and after operation are given, and the nurses present at the operation follow up the case at home and pay frequent visits. At the Hammersmith School Treatment Centre 1,608 children have been operated on with no mortality, direct or indirect; there has been one case of severe primary hæmorrhage which would have taken place in any hospital, whilst the few cases we have had of secondary hæmorrhage have occurred on the third to the seventh day, showing that twenty-four hours' detention in hospital would not have been of much service.

When one considers the large number of children—stupid, deaf, unhealthy, with restless, unrefreshing nights—who

are converted into normal beings by operation, to say nothing of those chronic otorrhoeas which often clear up like magic, ought we not to find matter for congratulation in the net result achieved, and not waste time in advocating the impossible?—I am, etc.,

WALTER E. FRY, M.R.C.S., L.R.C.P.,
Surgeon, L.C.C. Hammersmith School
Treatment Centre.

January 24th.

TUBERCULOUS MILK.

SIR,—Recent correspondence in your columns has revealed considerable diversity of opinion regarding the infectivity of bovine tuberculosis to man. At the last meeting of the Council of the Society of Medical Officers of Health representations on the subject were received from the Tuberculosis Group and individual members of the society, and the following resolutions were adopted unanimously:

- (a) That in the opinion of this society it has been conclusively proved that bovine tuberculosis is transmissible to children through the ingestion of infected milk.
- (b) That this society regards the evidence of immunization by the ingestion of living tubercle bacilli in milk as entirely unproved.

I was directed to forward you a copy of these resolutions for the information of your readers.—I am, etc.,

G. S. ELLISTON,
Executive Secretary, Society of Medical
Officers of Health.

1, Upper Montague Street, W.C.,
Jan. 22nd.

THE PREVENTION OF VENEREAL DISEASE.

SIR,—The present controversy regarding venereal disease prophylaxis would be welcomed by the medical profession if the protagonists would call a truce to recrimination and turn their minds to the more profitable channels of constructive policy. To this end they would do well to consider the last paragraph of Sir Archdall Reid's letter.

There are, in fact, two problems of venereal disease prophylaxis to be considered; the one dealing with the present generation is urgent and demands emergency measures. The Society for the Prevention of Venereal Disease is taking such measures. Their remedy is of necessity partial and imperfect, but so long as they realize that their method of attack is adapted only for the urgent needs of the moment, there can be little cause for concern about the effect on the morality of the people.

The second problem, affecting our children and generations yet unborn, requires more careful investigation and wider vision.

Now, there exist in this country three great institutions for the teaching of the young—the home, the Church, and the school. Of these, the home is the ideal place for early and continuous instruction in clean and healthy living; but, unfortunately, home teaching is not available at present on account of the ignorance of the parents themselves. The Church, however, is too preoccupied with creed and observance to realize that the teaching of conduct, rather than faith, is the crying need of our time. For the future it has great possibilities, but for the present we must trust to the school.

In school the growing child can be taught day by day the principles of three great sciences: History, dealing in broad outline with the development of the human race; biology, beginning with the everyday phenomena of plant and animal life, and leading up to the fundamental facts of human life and reproduction; and citizenship, the science of conduct, of the relation of individuals to one another, to the State, and to mankind. The teaching of a clean, healthy way of life is of immediate and paramount importance. In addition, the course of citizenship should include instruction on the great social problems of the day, among which that of venereal disease occupies a significant position.

It is the plain duty of the educational and medical authorities to unite in preparing a thorough systematic course on these lines. The matter is urgent.—I am, etc.,

Sherborne, Jan. 24th.

J. M. MACKINTOSH.

SIR,—Dr. Wansey Bayly, in your issue of January 1st, accused me of indifference to the ravages of venereal disease among the innocent. Such is not the case, and I think there is evidence in the correspondence in the last

few weeks to maintain the view that the innocent can, in the long run, only be protected by a high standard of honour among men. He also said that I ignore the problem as it exists at the present moment, and he then at once went back more than two years—to the war. The men who acquired venereal disease in the war were subjected to an intensity of temptation, combined with a shattering of the nervous system, such as is not the case to-day.

Venereal disease is the price that will always have to be paid for war, and the only way to prevent an epidemic of it in future is to work to prevent war. But it is the healthy young man entering on life to whom the Society for the Prevention of Venereal Disease is issuing its leaflets. To a man who has already acquired it, in the war or after, the word prevention does not apply, and no amount of leaflets or permanganate will prevent him from spreading the disease. His case is met by the venereal clinic.

The mere fact of advocating preventives assumes the possibility of a lapse. Once a man makes that admission he is unsafe and probably will run the risk, and, as the preventives are admittedly not absolutely certain, the fact of advocating them becomes a source of augmenting not decreasing disease. Dr. Otto May's parody in your issue of January 22nd hits the mark, and if one substitutes "Father, to John, aged 18," for "Mother, to Mary, aged 14," the case is complete. I trust that ridicule may be the best weapon to clear the air of this nauseous moral miasm that is being set loose in certain quarters.—I am, etc.,

London, S.E., Jan. 24th.

H. B. GLADSTONE.

MUSCLE RE-EDUCATION.

SIR,—The recent discussion on this subject in your pages ended by revealing apparently irreconcilable differences of opinion amongst different schools of experts as to the fundamental principles of muscular re-education. The question need not be left in this unsatisfactory position, since we have certain working hypotheses by which to test the claims made on behalf of any system of treatment of markedly disabled skeletal muscles. Thus the "submaximal exercise load" and the "limit of fatigue" are recognized guiding principles in all muscular work. Further, all are agreed that "voluntary contraction" of muscle has far more therapeutic value than any vicarious stimulation of the same induced by mechanical or electrical stimulation. There is also general agreement that "voluntary" exercise of a weak muscle should be selective for that muscle. The principles of the submaximal load, or the fatigue limit, and of a voluntary selective exercise, are of special importance in re-education of weak muscles.

Take now the Swedish system of re-education and the system described by Dr. W. Colin MacKenzie in his well-known book, and test the claims made for each by their compliance or otherwise with the principles outlined above. Assume that one is dealing with the case of a deltoid muscle disabled by myelitis of related spinal neurosis. A Swedish expert would treat a muscle in such a condition by massage, later by passive movements, and as the power of voluntary contraction returns by active eccentric and concentric movements, that is, by "isolation" contraction-relaxation of the weak muscle. All movements are guided by the expert. This system of treatment is thus based on the assumption that the patient cannot control and voluntarily exercise and accurately load his own muscle without the manual aid of the "teacher." Now there is nothing in what is known of the mechanics, physiology or psychology of the action and re-education of muscles which justifies such *a priori* assumptions. Apart from theoretical considerations we have the demonstrated fact that a patient can, by his own unaided voluntary effort, control and exercise and accurately load a disabled muscle from the beginning of the recovery of function. Colin MacKenzie describes fully one method whereby this may be done, and others employing the same or similar methods have confirmed the results obtained by him.

The advantages of the natural method of "free" uncontrolled over a manually-controlled method of training are very great. First, the patient's interest in and attention for the skilled work of retraining his own muscle is easily aroused and maintained; the process is one of "re-education" in the true sense of the term. Further, the patient puts on the exercise load, guiding his output of effort by

his own feeling of power, or want of power, in carrying out the movements prescribed by his teacher, and the output of effort is checked by the fatigue induced by the exercise. Overloading and overwork are by these means avoided. Most important of all is the demonstration which we owe to Colin MacKenzie, that voluntary selective exercise of the muscle can be successfully carried out from the commencement of recovery of function of the "injured" anterior neurones—that is, in the hypothetical case we are considering. The rhythm of rest and exercise must, of course, be skilfully adapted to the functional condition of the muscle and postural rest must be maintained continuously between the intervals of selective exercise. Under the Swedish system exercise is not "voluntary" in any psychological sense of the term. The Swedish expert puts on the muscle load according to his (the expert's) estimate of the power, or want of power, of the muscle, and the fatigue limit of exercise may readily be passed.

By selective exercise is meant that the muscle undergoing training is made to do work as prime mover or as fixative muscle. This selective training with postural rest is continued until the muscle is capable of doing full postural and phasic work in free movement or fixation of the part. Space does not permit me to discuss the relation of reflex "unconscious" and automatic and voluntary associative re-education to the selective process I have been considering, or impediments to the re-educative processes.

No skill in re-education will recreate a completely atrophied spinal neurone. But there is every reason to believe that excessive postural and phasic exercise of the muscle may result in atrophy of recovering neurones and in elongation and atrophy of the muscle, with resulting dropped shoulder, wrist or foot, or other deformities and disabilities that are all too common late effects of the spinal anterior poliomyelitis. These results of unskilled re-education of function are mainly due to the failure to realize the cardinal importance of the principle of the submaximal exercise load and the great value of selective free voluntary exercise in the retraining of disabled muscles. I have employed, or seen employed, the Swedish method and the electrical-contraction method in large numbers of cases of muscular disabilities, and I owe to Dr. C. MacKay an introduction to the method of Colin MacKenzie. I have employed this latter method, modified as experience indicated, in cases of infantile paralysis and in a large number of cases of locomotor disability resulting from war wounds, and I have come to recognize the great value of the clinical research work of Colin MacKenzie. Is it too much to hope that we will soon hear the last of the Battle of the Schools—whether Swedish, German or another—and that all re-education experts will concentrate on scientific research into the many still obscure problems of re-education of function of neuro-muscular and muscular disabilities?—I am, etc.,

C. FOREES,

Late M.O. for Re-education of Muscles, Alder Hey Military Hospital, Liverpool.

Aberdeen, Jan. 16th.

PATENT DUCTUS ARTERIOSUS.

SIR,—I read with interest in your issue of December 25th, 1920, Dr. Carey Coombs's account of four cases which lived to adult life; and, in your number of January 15th, Mr. Wilson Hall recalls three infantile cases.

The latter observer noted that no bruit could be heard in any of his cases, and in the only case I have seen I made a similar observation.

This was an infant in the first day of life. He cried lustily at birth, but within an hour became dyspnoeic and cyanosed, when I was called in by the midwife in attendance. The heart was beating forcibly, but no murmur was audible. All attempts at artificial respiration were fruitless, and at autopsy a wide patent ductus arteriosus was found connecting the left pulmonary artery with the commencement of the descending aorta.

A very interesting point in the case is that this was the third child the mother had lost in this way—namely, progressive dyspnoea and cyanosis, leading to a fatal termination; the first child lived two weeks, and the second three days. I was not in attendance on either occasion, and, unfortunately, no necropsies were performed, so that the diagnosis cannot be regarded as certain, but from her description I have no reason to doubt that a similar condition was present.

She has one living, healthy child, but this was by her first husband. A physical examination of her present husband revealed nothing which might throw a light on the mystery.—I am, etc.,

Surbiton, Jan. 18th.

A. R. C. DOORLY, M.B., B.S. Lond.

THE NAVAL MEDICAL SERVICE.

Sir,—I have seen no reply up to date to the letter of six aggrieved naval medical officers, dated December 1st, which appeared in your JOURNAL of December 11th. I quite agree with them in principle, but I would like to qualify two of their points. In the first place—"It is an undisputed fact that the great majority of newly qualified men who join the branch do so with no knowledge of the service." I agree with that, but the same thing applies to every other branch, and moreover, the medical student is often impressed with the idea that there is nothing to do in the navy, with a nice pension to look forward to after years of leisure. This attracts a class of man who is no use either in or out of the service. Such men after joining just sit down and grumble, and in the meantime neglect the opportunities which are at hand. In regard to "status" with the executive officer, a medical officer's status is just what he makes it; the status of the idler and grumbler is not high.

There are two sides to every question. What has the average naval surgeon done for the service? What is his status with the general medical profession? Without the British Medical Association at his back, how would he stand on his own merits? He has no grounds for comparing the Naval Medical Service with the Army Medical Service. The British Royal Army Medical Corps has made itself a pattern of efficiency to the rest of the world by hard work and by making a special study of the requirements of the service. They have justly earned any emoluments they have got. Contrast with the navy. Naval medical officers, with some exceptions, have not adapted themselves to their surroundings. They have not sufficiently considered the requirements of naval service. They have in turn compared their position with the army surgeon and the civil practitioner without realizing that the requirements of the navy are as special and as different from either as the work of the army surgeon is from the civil.

Granted that clinical material is lacking in the navy, interesting clinical material is not the stuff a navy is made of—nor a nation, for that matter; but surely the navy offers other fields of greater usefulness and of equal interest to a medical officer. Men in the navy are passed in as physically fit. It is our job, therefore, to keep them fit. A study of the diseases prevalent in the navy shows that they are, to a great extent, preventable, and yet what have we done in that direction? The subject is a life's study. Lind, Trotter and Blane, our illustrious predecessors of the last century, pointed out the way. Had we followed their example, the Naval Medical Service would not be in its present humble position; we should not have to look to other countries for information on the ventilation of ships; we should not have to grumble about recognition, about status, about pay, about honours, etc. We should have won everything on our merits. Every workman is worthy of his wage.

It is high time, therefore, that we put an end to grumbling and put our heads together to set about making the Naval Medical Service a worthy unit of the great service to which we belong. The rest will follow.—I am, etc.,

January 24th.

SURGEON COMMANDER, R.N.

Universities and Colleges.

UNIVERSITY OF OXFORD.

Lectures in Clinical Medicine and Surgery.

THE Regius Professor of Medicine, Sir Archibald E. Garrod, K.C.M.G., is conducting a course of clinical lectures on Tuesdays, at 2.30 p.m., at the Radcliffe Infirmary. Courses of clinical lectures are also being given by the Litchfield Lecturer in Medicine, Dr. W. Collier, and by the Litchfield Lecturer in Surgery, Mr. A. P. Dodds-Parker, F.R.C.S.

Scholarships in Natural Science.
An examination for scholarships in natural science is announced at Merton, Exeter, New, Brasenose, and Corpus Christi Colleges, beginning on June 28th.

At Jesus College the following elections to exhibitions in natural science are announced: G. M. Dyson, C. Hutton, K. P. Osborne, M. H. Evans, W. G. Rees, H. W. Jones.

At a congregation held on January 20th the degree of Bachelor of Medicine was conferred on T. S. Nelson and H. G. Burford.

UNIVERSITY OF CAMBRIDGE.

At a congregation held on January 21st the following medical degrees were conferred:

M.B., B.Ch.—R. C. P. Whitcombe, D. W. R. Richardson, W. S. Sykes.
B.Ch.—J. M. Lawrie, J. L. Potts, F. S. Maclean, F. G. Wood, G. P. N. Richardson.

UNIVERSITY OF LONDON.

LONDON HOSPITAL.

THE Liddle Triennial Prize, in the gift of the London Hospital, has been awarded to Surgeon Commander S. F. Dudley, O.B.E., M.D., R.N., and Professor James McIntosh, M.D.

UNIVERSITY OF EDINBURGH.

A MEETING of the University Court was held on January 17th. Professor Lorrain Smith, Dean of the Faculty of Medicine, was elected one of the delegates to a Congress of the Universities of the Empire to be held in London and Oxford in July. Dr. J. Stewart Fowler, a senior lecturer in the Faculty of Medicine, was appointed a member of the Faculty. It was agreed to revive the course on advanced morphology of the vertebrata, which had been suspended since 1914. Dr. Henry Yellowlees and Dr. William M'Alistair were appointed university assistants to the Professor of Psychiatry.

Dr. H. D. Wright, of the Department of Pathology, has tendered his resignation on appointment as assistant to the Superintendent of the Laboratory of the Royal College of Physicians. Professor Kynoch has been appointed joint representative of the University Courts of the Universities of St. Andrews and Edinburgh on the Central Midwives Board for Scotland.

UNIVERSITY OF MANCHESTER.

PROFESSOR SIR WILLIAM THORBURN has resigned the Chair of Clinical Surgery, and at the last meeting of the Council and Senate the following resolution was passed:

That the Council and Senate have heard with deep regret of the resignation by Sir William Thorburn, C.B., K.B.E., M.D., F.R.C.S., of his position as senior honorary surgeon to the Manchester Royal Infirmary, which involves also his resignation of the Chair of Clinical Surgery in the University. The Council and Senate desire, to express to Sir William Thorburn their high appreciation of the great services which he has rendered to the university during his long connexion with it as a teacher; of the contributions he has made to the advancement of knowledge in surgery, and of his distinguished record and skill in the practice of his profession. The regret which Sir William Thorburn's friends and colleagues feel at the termination of his official connexion with them is increased as they recall the high qualities and devotion which he has brought to the administrative side of his university work, and the geniality and consideration which he has always shown towards his colleagues.

The University Prize in Medicine has been awarded to L. J. Wits.

Dr. A. H. Holmes and Mr. Geoffrey Jefferson, M.S., F.R.C.S., have been appointed lecturers in applied anatomy.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

HUNTERIAN LECTURES.

THE following arrangements are announced for the forthcoming Hunterian Lectures to be delivered in the theatre of the college, Lincoln's Inn Fields, at 5 p.m.: Mr. W. Sampson Handley will give one lecture on the pathology and surgery of lupus on Monday next, January 31st; Mr. W. G. Howarth will give one lecture on mucocoele and pyocoele of the nasal accessory sinuses on Wednesday, February 2nd; Mr. C. W. Gordon Bryan will give one lecture on injuries of the diaphragm, with special reference to wounds jointly involving thoracic and abdominal viscera, on Friday, February 4th.

LONDON INTERCOLLEGIATE SCHOLARSHIPS.

THE London Intercollegiate Scholarships Board announce that twenty-three scholarships and exhibitions of an aggregate value of about £2,450, open to men and women, and tenable in the Faculties of Arts, Science, Medical Sciences, and Engineering of University College, King's College, East London College, and Bedford College, will be offered for competition on May 3rd next.

Seventeen medical entrance scholarships and exhibitions, of an aggregate value of about £1,580, tenable in the Faculty of Medical Sciences of University College and King's College, and in the Medical Schools of Westminster Hospital, King's College Hospital, University College Hospital, the London (Royal Free Hospital) School of Medicine for Women, and the London Hospital, will be offered for competition on June 28th.

Full particulars and entry forms may be obtained from the Secretary of the Board, S. C. Ranner, M.A., The Medical School, King's College Hospital, Denmark Hill, London, S.E.5.

Obituary.

DAVID YELLOWLEES, M.D. EDIN., LL.D. GLASG.,
Late Physician-Superintendent, Royal Glasgow Asylum.

THE death took place, at Edinburgh, in his eighty-fifth year, of Dr. David Yellowlees, formerly physician-superintendent of the Royal Glasgow Asylum, Gartnavel. Dr. Yellowlees was a native of Stirling, where he received his early education, and he proceeded to Edinburgh University, graduating M.D. in 1857. After an appointment as house-surgeon at Edinburgh Royal Infirmary and a period of study in Paris he became assistant to Sir William Gairdner, physician to the Edinburgh Royal Infirmary. Later he was appointed assistant physician at the Royal Edinburgh Asylum, Morningside, remaining there until 1863. In that year he became superintendent of the Glamorgan County Asylum, where he remained twelve years, building up a reputation as an administrator and physician of distinction.

In 1875 Dr. Yellowlees was appointed physician-superintendent of the Royal Glasgow Asylum, Gartnavel, a post which he held till his retirement in 1902. Under his administration this institution grew and flourished, and Dr. Yellowlees became well known throughout Scotland as a consultant in mental diseases. He was lecturer on insanity at Glasgow University; president of the Psychological Section of the British Medical Association at the Glasgow Meeting in 1885; and president of the Faculty of Physicians and Surgeons of Glasgow during 1892-94. In 1888 he received the degree of LL.D. from the University of Glasgow. In addition to the many marks of recognition he received in this country, he was elected an honorary member of the American Medico-Psychological Association, of the Moscow Society of Neurological and Mental Diseases, and of other foreign societies. Dr. Yellowlees took a leading part in the philanthropic life of Glasgow; since 1910 he had been chairman of the Broomhill Home for Incurables; he was one of the founders of the Glasgow Association for the Care of Defective and Feeble-minded Children; he was active in the inauguration of the Lanfine Home for Advanced Cases of Consumption; and he took a warm interest in many other branches of public work. He was highly esteemed for his strong common sense and his high sense of duty by all who knew him in connexion with public affairs, while his deep religious convictions moulded and coloured his whole life.

After his retirement Dr. Yellowlees continued to live in Glasgow until the autumn of 1919, when he removed to Edinburgh. He is survived by his wife, his daughter, and two sons, one of whom is Dr. David Yellowlees of Stirling, and the other Dr. Henry Yellowlees, senior assistant physician at the Royal Edinburgh Asylum, Morningside.

RUPERT FARRANT, M.C., F.R.C.S. ENG.,
Late Assistant Surgeon, Westminster Hospital.
